For Andrea and Finn. Both of you fuel my passion and motivation for this endeavor. I cannot thank you enough.

Mark Krause

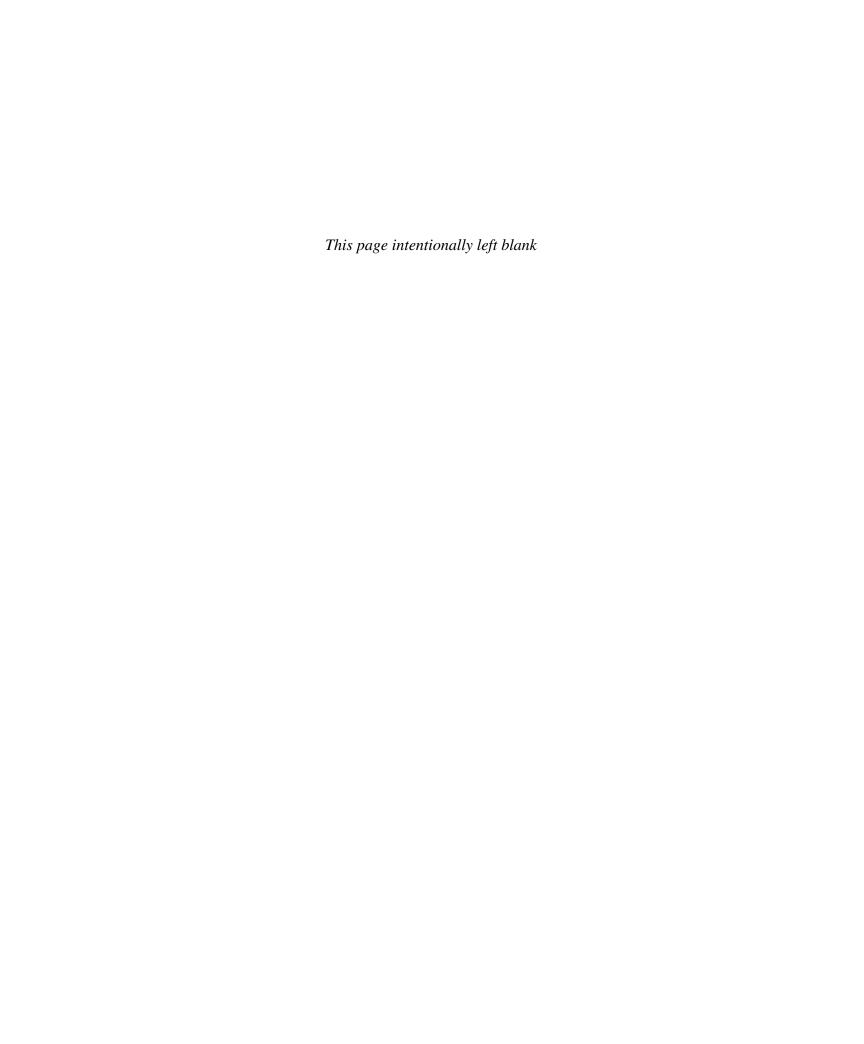

To Kim, Sophie, and Jonah, for your patience, understanding, and forgiveness during all the hours this project has occupied me.

Dan Corts

# About the Authors

Dr. Mark Krause received his Bachelor's and Master's degrees at Central Washington University, and his PhD at the University of Tennessee in 2000. He completed a post-doctoral appointment at the University of Texas at Austin where he studied classical conditioning of sexual behavior in

birds. Following this, Krause accepted a research fellowship through the National Institute of Aging to conduct research on cognitive neuroscience at Oregon Health and Sciences University. He has conducted research and published on pointing and communication in chimpanzees, predatory behavior in snakes, the behavioral and evolutionary basis of conditioned sexual behavior, and the influence of testosterone on cognition and brain function. Krause began his teaching career as a doctoral candidate and continued to pursue this passion even during research appointments. His teaching includes courses in general psychology, learning and memory, and behavioral neuroscience. Krause is currently a professor of psychology at Southern Oregon University, where his focus is on teaching, writing, and supervising student research. His spare time is spent with his family, cycling, reading, and enjoying Oregon's outdoors.

Dr. Daniel Corts discovered psychology at Belmont University where he received his B.S. He completed a PhD in Experimental Psychology at the University of Tennessee in 1999 and then a post-doctoral position at Furman University for one year where he focused on the teaching of

psychology. He is now professor of psychology at Augustana College in Rock Island, IL where he has taught for over 15 years. His research interests in cognition have lead to publications on language, gesture, and memory, and he has also published in the area of college student development. Corts is increasingly involved in applied work, developing programming and assessments related to K-12 educational programming and teacher preparation. Corts is enthusiastic about getting students involved in research and has supervised or coauthored over 100 conference presentations with undergraduates. Corts has served as the local Psi Chi advisor for a dozen years and has served on the Board of Directors for several years, including his current term as President. In his spare time, he enjoys spending time with his two children, traveling, camping, and cooking.

# From the Authors

Welcome to the second edition of *Psychological Science: Modeling Scientific Literacy!* It is a great privilege for us to offer an updated and revised version of our textbook. Much has happened in psychology since the first edition and we are excited to present the latest and greatest that our field has to offer. Of course, equally if not more important to keeping up with the science is ensuring that our readers find our book accessible, interesting, and hopefully inspiring. To this end we have, as authors should, put ourselves in the mindset of a college student first encountering this material and re-read the entire book. There is no better way to begin the process of revising and improving a textbook. In the second edition we have continued our emphasis on

helping the reader organize and assess their thinking and learning about the material. Each module includes learning objectives of increasing depth (knowing, understanding, analyzing and applying) and end of module quiz and chapter items assessing learning at each level. Also new to this edition are journal prompts in each module which prime students to think deeply about specific topics, take a stance on an issue, or apply a concept to oneself.

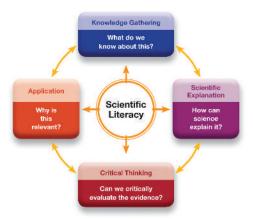

We firmly believe that a well-rounded college education requires a healthy dose of science. This is true regardless of an individual's personal and career goals. To this end, *Psychological Science* is written from the perspective of scientific literacy—the ability not only to define scientific

terminology, but also to understand how it functions, to critically evaluate it, and to apply it to personal and societal matters. Scientific literacy comprises four interrelated components:

- 1. knowledge: what do we know about a phenomenon?
- **2. scientific explanation:** how does science explain the psychological process we are examining?
- **3. critical thinking:** how do we interpret and evaluate all types of information, including scientific reporting?
- **4. application:** how does research apply to your own life and to society?

Psychological Science presents students with a model for scientific literacy; this model forms the core of how this book is written and organized. We believe a scientific literacy perspective and model will prove useful in addressing two course needs we often hear from instructors—to provide students with a systematic way to categorize the overwhelming amount of information they are confronted with, and to cultivate their curiosity and help them understand the relevance, practicality, and immense appeal of psychological science.

Psychological Science models the processes of scientific thinking. As was the case in the first edition, the elements of scientific literacy are explicitly demonstrated once per module, and implicitly throughout. We are very excited to introduce a new feature for the second edition: the Scientific Literacy Challenge. At the end of each chapter students can practice applying scientific and critical thinking to an important, contemporary issue. We tackle such topics as free-range parenting, cognitive enhancement drugs, college admissions testing, and brain training websites. Students are asked to read author created blog entries, editorials, or advertisements about these topics and evaluate them from a scientific literacy perspective through journal prompts, and multiple-choice, matching and true/false questions.

We thank the many instructors and students who have helped us craft this model and apply it to our discipline, and we look forward to your feedback. Please feel free to contact us and share your experiences with the 2nd edition of *Psychological Science*.

Mark Krause krausema@sou.edu

Daniel Corts danielcorts@augustana.edu

#### What's New?

The Scientific Literacy Challenge described above is an exciting new feature of the second edition. We also updated module openers to include contemporary and relevant examples, and updated research, and in some cases replaced, topics covered in the Working the Scientific Literacy Model features within each module. Naturally, the topics we cover involve ongoing and exciting research. Therefore, each chapter has been updated accordingly, and, in many places, we have added new topics we felt deserve inclusion in our book. For example:

- Chapter 1, "Introducing Psychological Science" includes additional instruction on critically thinking about sources. Students learn to evaluate a message by considering the author or speaker, the purpose of the article, the publisher or presenter, and other factors that affect the reliability and quality of the message. Interactive exercises help students understand the ways in which psychology may be expanded into other fields, such as sports psychology.
- Chapter 2, "Reading and Evaluating Scientific Research" provides additional tools to think about and understand the outcomes of research. The coverage of correlational methods is supplemented by instruction on how to think about what it means to be a small, medium, or large correlation. Similar improvements have been made to the discussion on how to understand group differences in experimental and quasiexperimental research.
- Chapter 3, "Biological Psychology" now begins by asking students to think about Paleo diets as a way to introduce evolutionary psychology. There is a new section introducing epigenetics. Citations and coverage have been expanded on topics of genomics, neurogenesis and brain plasticity, and brain imaging technology.

- · Chapter 4, "Sensation and Perception" includes new interactive features for applying signal detection theory and monocular depth cues, and updated research and coverage of subliminal perception, multi-tasking, phantom limb therapies, and object recognition.
- Chapter 5, "Consciousness" includes a new Working the Scientific Literacy Model feature on the neurocognitive theory of dreaming, updated coverage on how marijuana and other drugs affect cognition, new research on dream sleep and memory, and the therapeutic effects of hypnosis and meditation.
- Chapter 6, "Learning" includes updated coverage on applications of classical conditioning; including taste aversions, advertisement, drug tolerance, intext activities for practicing concepts of classical and operant conditioning, updated research and expanded personal application opportunities on topics of cognitive and long-term learning, a revised Working the Scientific Literacy Model feature to balance coverage of research on video game playing and violent behavior.
- Chapter 7, "Memory" has more coverage of applications including strengthening memories and the reliability of eyewitness testimony.
- Chapter 8, "Thought and Language" makes more connections between the often very abstract theories of reasoning and daily experience. For example, students can learn about individual differences in the reliance on representativeness, and how these differences relate to interest in superstition, the paranormal, and conspiracy theories.
- Chapter 9, "Intelligence and Aptitude, and Cognitive Abilities" includes updated citations and research, especially when covering intelligence and the brain. Also, students can engage in a debate on whether colleges and universities should consider personality tests as a supplement to or even a replacement for traditional college aptitude tests.
- Chapter 10, "Life Span Development" includes updated coverage of preterm infant development, child cognitive development, expanded and updated coverage of adolescent sexuality, brain development, and identity.

- Chapter 11, "Motivation and Emotion" includes updated research on sex and the brain, and sexual orientation, neural and psychological bases of hunger and eating, effects of loneliness and mental and physical health, and an in-text activity on achievement motivation.
- Chapter 12, "Personality" includes updated coverage of cultural and evolutionary influences on personality, practice application activities for the Big 5, cultural variation, and psychodynamic views on personality, updated discussion on scientific research on suppression and critical analysis of Freud's views on personality.
- Chapter 13, "Psychological Disorders" has been updated throughout to reflect DSM 5 revisions and recent prevalence statistics when available.
- Chapter 14, "Therapies" includes a new Working the Scientific Literacy Model feature about the use of mobile apps designed to improve mental health, updated coverage of topics such as empirically supported treatments, precision medicine and cultural factors related to drug treatments, effects of nutrients such as Omega-3 fatty acids on health, and reduced emphasis on outdated anti-depressant drugs and expanded coverage of potential new treatments (e.g., low-dose ketamine).
- Chapter 15, "Social Psychology" has updated and modified coverage of stereotypes and person perception. This reflects increased national awareness of the use of force by law enforcement, an extremely important topic that is also very engaging for students.
- Chapter 16, "Health, Stress, and Coping" has updated coverage on the effects of media exposure on health related behaviors (smoking), social contagion effects occurring via social media (Facebook), effects of stress on cognitive processes, posttraumatic growth, effects of exercise and nutrition on cognitive functioning.
- Chapter 17, "Industrial and Organizational Psychology" includes substantial updates to sections on selection and assessment. There is increased linkage between the sections on employee affect and leadership through an interactive investigation of how money may or may not be a useful motivator for employees.

# **Content and Features**

Students in the general psychology course are inundated with many disparate pieces of information at a time when they are still developing the skills and strategies for organizing and making sense of that information. How do Working the Scientific Literacy Model and supporting features in *Psychological Science* address this issue?

#### **Knowledge Gathering**

#### What do we know about this?

Introductory psychology courses cover a vast amount of content drawn from diverse specialty areas. The organization of the material is central to helping students absorb this content.

#### Modules ⊢

Chapters are divided into modules to make it easier for students to organize content as well as to self-test and review their learning at regular intervals. For instructors, the modular content makes it easy to customize their delivery based on their preferred syllabus.

Module 2.1 Principles of Scientific Research

Learning Objectives

- **2.1a** Know . . . the key terminology related to the principles of scientific research.
- quality scientific research.

  2.1c Understand . . . how biases might influence
- Several spars ago, the Society for Neuroscience initial that Datal Launa, the primite laster of Theorem Haddhims, it, their annual emerging science neering in disease the practice of the property of the property of the property of the sease of the property of the property of the control by individuals entails the scientific community, it is life that no more than a lamberd—for of practice—otherscend that no more than a lamberd—for of practice—otherscend that no more than a lamberd—for of the sector in the subject. Why, then, would the Society invite the Dala Launa to speak short a begin that we design and the science? 2.1d Apply . . . the concepts of reliability and validity to examples.

figures, and common sense are reliably truthful sources of information.

of careful observations and manuscream, there really is no scription, and significant contribution, and the contribution, except the contribution of the contribution of the contribution, extension and the interested in modification. In recent upon, certains should be interested in modification in recent upon, and the contribution of the contribution of the contribution of the book for how septic benefit under the contribution of the should be few to see that the contribution of the contribution of modification into physical and psychological word-body; in the should for how septic benefit under the contribution of the temperature of the contribution of the contribution of the contribution of the time of the contribution of the contribut

## Learning Objectives

Learning Objectives are organized around an updated Bloom's taxonomy that aims to guide students to higher-level understanding. Summaries of the key points related to these objectives are provided at the end of each module. Objectives are listed at four levels of increasing complexity: know, understand, apply, and analyze.

## Module Summaries

The major terms, concepts, and applications of the modules are reviewed in the Module Summaries. The summaries also return to and address the original Learning Objectives from the beginning of the module and include application questions. Answers to end-of-module and end-of-chapter assessment can be found in the Instructor's Manual.

#### Module 2.1 Summary

2.1a Know... the key terminology related to the principles of scientific research:

anecdotal evidence appeal to authority appeal to common sense convenience samples demand characteristics double-blind study ecological validity

objective measurements operational definition peer review placebo effect population random sample reliability replication

ralidity rariable

Scientific research.

These characteristics include (1) that measurements a chiective valid and reliable (2) the research can be seen

objective, valid, and reliable; (2) the research can be generalized, (1) it use schniques that reduce bias; (4) the findings are made public; and (5) the results can be replicated. For example, objective, valid, and reliable measurements for example, objective, valid, and reliable measurements can be readed to the results of the resul

#### 1c Understand . . . how biases might influence the stcome of a study.

Demand characteristics affect how participants respond research studies. Understandably, they often attempt to otrary themselves in a positive light, even if that means of answering questions or behaving in a fully truthful namer. Researchers can also influence the outcomes of neir own studies, even unintentionally.

2.1d Apply... the concepts of reliability and validity to examples.

cliable and valid measures are essential to scientific sessenth. Table 2.1 on page 35 provided an opportunity to ppby your knowledge. In the first example, Dr. Tatum had improve reliability, although her physiological instrutents measured what they were supposed to (validity), the placed reliability because they were inconsistent. In nother example, Dr. Nielsen questioned the validity of his between the placed reliability of the properties of the placed to the placed reliability, there was represented the properties of the placed to the pla

2.1e Analyze . . . whether anecdotes, authority figures and common sense are reliably truthful sources of information.

To evaluate evidence, you should ask several questions. First, is support for the claim based on the words or endorsement of an authority figure? Endorsement by an authority is not necessarily a bott thing, as someone who is an authority (espert) at something, should be able to back up the claim. But the authority of the individual alone is not satisfactory, especially if data port of the control of the control of the control of the port the claim. Seemed, is sometine supplying encoded and evidence? As convincing as a personal testimony may be, aneeded a evidence is not sufficient for backing and claim that can be scientifically tested. Common sense also has its place in daily life, but by itself is insufficient as a final explanation for anything. Explanations based on good scientific sessarish should override those based jects. By examining and reporting an average effect for that group, psychologists can get a much better sense of how individuals are likely to behave. But how large of a group is it possible to study? Ideally, it would be best to study an entire population—the group that researchers want to generalize about. In reality, the task of finding all population members, persuading them to participate, and measuring their behavior is impossible in most cases. Instead, psychologists typically study a sample—a select

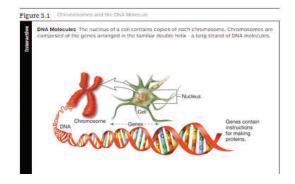

## → Key Terms

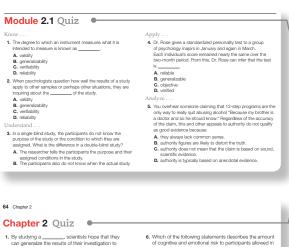

Key Terms are defined within the narrative, helping students place them in context, and are then listed again within the Module Summaries. A complete glossary is also included at the end of the text.

#### REVELTM

Fully digital and highly engaging, REVEL offers an immersive learning experience designed for the way today's students read, think, and learn. Enlivening course content with media interactives and assessments, REVEL empowers educators to increase engagement with the course, and to better connect with students: pearsonhighered.com/revel.

Most of the billions of cells in the human body include a nucleus that houses most of our genetic code (some additional DNA is located in a cellular structure called the mitochondrion). Genes are the basic units of heredity; they are responsible for guiding the process of creating the proteins that make up our physical structures and regulate development and physiological processes throughout the life span. Genes are organized along chromosomes 9, which are large molecules in the cellular nucleus that include the structures shaped like a double helix that are lined with all of the genes an individual inherits. Humans have approximately 30,000 genes distributed across 23 pairs of chromosomes, half contributed by the mother and half from the father (see Figure 3.10).

- Which of the following is an example of demand characteristics affecting an experiment?
   A. An experimenter draws the wrong conclusions from a study because she did not use the correstatistical analysis.

sample; population
 B. population; sample

C. convenience sample; random sample D. random sample; convenience sample

- statistical analysis.

  B. A participant change his response to a question because he has the feeling that the experimenter wants him to do so.

  C. An experimenter stops using a test because it does not appear to be reliable.

  D. A participant in a double-bind experiment believes she is in the control group
- 3. Why it is a bad idea to draw conclusions from anecdotal evidence?
- evidence?

  A. Such conclusions usually go against common
- sense.

  B. Anecdotes are reliable only if they come from experts, which they rarely do.

  C. Anecdotes are a single-blind technique, not a double-blind method.

- Which of the following statements describes the amount of cognitive and emotional risk to participants allowed in psychological research today?
   A. Any amount of risk is acceptable.
- No amount of risk is acceptable.
   A little risk is always acceptable, but more than minimal risk is never acceptable.
   The amount of acceptable risk depends in part on the likely benefits from the study.
- C. generally acceptable when absolutely necessary for
- Under which of the following circumstances would the mean be the best measure of central tendency to use?
   A. The data have a normal distribution.
   B. The data are positively skewed.
   C. The data are negatively skewed.
   D. The mean is always the best measure of central

- tendency.

  9. A teacher notices that on the last science test, some students did very well, while other students performed poorly or had grades in the middle of the pack. If she wanted to measure how "spread out" all of the scores were, which descriptive statistic could

## Module Quizzes End-of-Chapter Quizzes

Quizzes appear at the conclusion of modules and chapters. These quizzes contain multiple-choice questions that enable students to assess their comprehension and better prepare for exams. Like the Learning Objectives, the Module Quizzes assess understanding at the four levels of Bloom's taxonomy and are marked accordingly. Answers to quizzes can be found in the Instructor's Manual.

#### Scientific Explanation

#### How can science explain it?

This element of scientific literacy encompasses a basic understanding of research methodology and thinking about problems within a scientific framework. Psychological Science integrates and reinforces key research methodology concepts throughout the book. This interweaving of methodology encourages students to continue practicing their scientific thinking skills. As noted in the National Science Education Standards, learning science is more than accumulating facts; that is, students learn to ask questions, construct explanations, test those explanations, and communicate their ideas to others.

Module 2.1 Principles of Scientific Research

#### Learning Objectives

- 2.1a Know . . . the key terminology related to the principles of scientific research.
- 2.1b Understand . . . the five characteristics of quality scientific research.
- 2.1c Understand . . . how biases might influence the outcome of a study.
- Several years ago, the Society for Neuroscience invited the Dalai Lama, the spiritual leader of Tibetan Buddhism, to Datat Lamin, the sprittan leater of thetam Butanism, to their annual emerging science meeting to discuss the practice of meditation. For most people, meditation is understood to be a mystical, subjective, nonscientific practice embraced by individuals outside the scientific community. It is likely that no more than a hundred—if not fewer—of the Society's 30,000 plus members had a professional, scientific interest in the subject. Why, then, would the Society invite the Dalai Lama to speak about a topic that was clearly not based in science? Several hundred Society members were so opposed to the Dalai Lama's talk that they signed a petition to can cel his scheduled appearance. But according to the Dalai Lama, the members' opposing opinions about the value of meditation are rooted in the same thing: an almost complete lack of understanding of the practice. Without the benefit
- **2.1d** Apply . . . the concepts of reliability and validity to examples.
- 2.1e Analyze . . . whether anecdotes, authority figures, and common sense are reliably truthful sources of information.

of careful observations and measurement, there really is no scientific way of saying whether meditation is worthwhile. Therefore, it is precisely this lack of understanding why scinetropie, it is precisely into auxo, printersamaning way ser-entists should be interested in meditation. In recent years, neuroscientists such as Richard Davidson and Antoine Lut-of the University of Wisconsin have confirmed that medita-tion does have numerous benefits. They have also developed tion does have numerous contrist. Incy nave asso accessoped models for how specific brain functions translate the practice of meditation into physical and psychological well-being. In Chapter I, we argued that critical thinkers should be skeptical, as many Society members demonstrated. However, we also argued that critical thinkers should be curious and that their opinions should be modified to fit the evidence that their Opinions stouds of modified to Ji the content.e-something that Davidson, Lutz, and colleagues are working toward. In this chapter we turn to the process of gathering and evaluating evidence.

Module Opening Vignettes +

Each module opens with a short vignette emphasizing the personal and societal relevance of certain topics to be covered.

## Myths in Mind +

Many commonly held beliefs people have about behavior before taking a psychology course are half-truths or outright falsehoods. This feature sets the record straight in a concise and informative way. The selected examples are likely to have personal relevance to many readers and deal with important scientific issues.

#### Myths in Mind

#### We Are Born With All the Brain Cells We Will Ever Have

cells could generate once an organism was born. This conclusion made perfect sense because no one had ever seen new neurons form in adults, and severe neurological damage is often permanent. Advances in brain science have challenged this belief (Gage, 2000). Researchers have observed neurogenesis, beinet (cagge, cook), reassent lets i nave classified in developerass, which is the formation of new nerve cells, in severel brain areas of rodents, monkeys, and humans (Beaun & Jessberger, 2014). The growth of a new cell, including neurons that populate a few different brain regions as well as some glid cells, starts with stem cells, which are unique types of cells that do not have a special-

Until the 1960s neuroscientists were unaware that new nerve ized, genetically programmed function. When a stem cell divide the resulting cells can become part of just about anything—bone, kidney, or brain tissue. What determines the type of nerve cell that develops and its migratory path within the brain is the stem cell's external chemical environment (Williams, Holman, & Klein, 2014). Our increased understanding of neurogenesis has raised config. Our increased understanding on inducing least assets as severe exciting possibilities; perhaps scientists can discover how to trigger neural growth in parts of the nervous system that do not naturally undergo neurogenesis throughout the life span. Developments in neural stem-cell research can bring added hope for recovery from brain injury and disease.

In recent years, an increasing number of instructors have begun to focus on telling students how psychological science fits within the scientific community. Psychology serves, in essence, as a hub science. Through this emphasis on scientific literacy in psychology, students begin to see the practicality and relevance of psychology and become more literate in the fields that our hub science supports.

#### **Critical Thinking**

#### Can we critically evaluate the evidence?

Many departments are focusing to an increasing extent on the development of critical thinking, as these skills are highly sought after in society and the workforce. Critical thinking is generally defined as the ability to apply knowledge, use information in new ways, analyze situations and concepts, and evaluate decisions. To develop critical thinking, the module objectives and quizzes are built around an updated Bloom's taxonomy. Objectives are listed at four levels of increasing complexity: know, understand, apply, and analyze. The following features also help students organize, analyze, and synthesize information. Collectively, these features encourage students to connect different levels of understanding with specific objectives and quiz questions.

#### Object Recognition

Objects in our world can be seen from many different perspectives—that is, they can be seen from many different perspectives—that is, they can be seen from near or far under varying levels of light, and from different angles. Given the numerous variations in how objects can be sensed, how is it that we still perceive them in the same, unified way?

What do we know about object

recognition?

Despite the diverse ways that an object can be sensed, it is still perceived as the same object. This observation highlights what is called perceptual constancy, the highlights what is called perceptual constancy, the highlight is perceive objects as huring constant shape, size, and other despite clumges in perspective. What makes perceptual constancy, possible is our ability to make relative judgments about shape, size, and lightness. For efshape constancy, we judge the angle of the object relative to ur position (see Figure 4.16). Color constancy allows us to recognize an object's color under varying levels us to recognize an object's color under varying levels of illumination. For example, a higher set of illumination. For example, a higher set of the solution of the set of t Size constancy is based on judgments of how close an object is relative to one's position as well as to the posi-tions of other objects. Also, our perception of objects involves distinguishing them individually, and identi-fying objects that appear frequently or rarely. As it turns

object recognition occurs?

Object recognition occurs:

Psychologists who specialize in visual perception have attempted to identify conditions in which we are likely to succeed or fail to perceive objects. It turns out that the encuency with which we encounter objects is closely related to our preception of them.

To see how, view the stimulus in Figure 4.17. Scatterida around the dark background are offset 1.5. One of the objects, however, is actually a T. It is easy to spot and only

## Working the Scientific Literacy Model

Working the Scientific Literacy Model, introduced in Chapters 1 and 2, and then featured in each module in the remaining chapters, fully integrates the model of scientific literacy. Core concepts are highlighted and students are walked through the steps of knowledge gathering, approaching the problem from a scientific standpoint, using critical thinking, and revealing applications.

#### Module 4.5 Scientific Literacy Challenge: Distracted Drivers

Cell phones made their first appearance in the retail market as car phones. Units had to be mounted in the interior of a vehicle and wired into its electrical system; they were literally part of the car. Incontacily, there is now evidence suggesting that a car is the less place a cell phone should be. You have probably heard arguments in favor of banning drivers from using cell phones, and most states have enacted lavos to carb their usage—specially for texting.

Before you start this activity, take a minute to write your thoughts about using a cell phone while driving.

#### What do we know about distracted driving?

Read the following letter from a consumer advocacy group. Make sure you understand the boldfaced terms and concepts from Chapter 4 and that you have a clear sense of what the writer is claiming.

By Vanessa Fowler, President, Federation of American Drivers

Dear Representative,

I am writing on behalf of the 220,000 members of the Federation of American Drivers (FAD) who, as a group, are concerned about a major thmat to public safety: "Distracted drivers," who are responsible for more than 3,000 traffic deaths annually, and more than 420,000 significant injuries. Drivers face a barrage of sights and sounds that divide attention. Only a portion of these are relevant to driving; the rest are distractions, and few are as powerful and ubsiquitous as the cell phone. FADP possition is that cell phone use should be completely banned for drivers of any age, any vehicle, on any public acadway. While several US states and territories have taken steps in that their clinch for too few have enacted a complete ban. Many people assume that the problem with cell phone use is limited to texting or conversations that require at least one hand off the wheel. However, data show that procecupied hands are not the problem. The enal issue is that cell phones —including texting, talking, or using apps—demands that the user selectively attends to the task, which can block out virtually everything else. For drivers, that means blocking out the traffic, instruments on the dashboard, and pedestrians or cyclists. Scientists have shown that people are so good at selecting what to attend to that they can experience inattentional blindness. In other words, a driver can be unaware of something they are looking directly at, simply because their attention is on their phone.

The FAD is advocating a very strict position on cell phones, one that they know will meet a lot of resistance. Read on to see what kinds of evidence they cite to support their argument.

## Scientific Literacy Challenge

At the end of each chapter, students can practice applying scientific and critical thinking to an important, contemporary issue such as free-range parenting, cognitive enhancement drugs, college admissions testing, and brain training websites. Students are asked to read author created blog entries, editorials, or advertisements about these topics and evaluate them from a scientific literacy perspective through journal prompts and multiple-choice, matching, and true/false questions.

## Application

#### Why is this relevant?

Psychology is a highly relevant, modern science. To be scientifically literate, students should relate psychological concepts to their own lives, making decisions based on knowledge, sound methodology, and skilled interpretation of information.

# For Instructors

SCIENTIFIC LITERACY is a key course goal for many introductory psychology instructors.

Learning science is an active process. How do we help instructors model scientific literacy in the classroom and online in a way that meets the needs of today's students?

## Organization

Instructors consistently tell us one of the main challenges they face when teaching the introductory psychology course is organizing engaging, current, and relevant materials to span the breadth of content covered. How do we help organize and access valuable course materials?

#### Revel

Reading has been the cornerstone of education since the advent of the printing press. Yet despite our world becoming ever more technologically interconnected, the ways in which learners and educators interact with the written word have remained largely static. With REVEL from Pearson, a new learning experience can begin. Through our interactions with customers around etexts, videos, and powerful reporting tools, we arrived at REVEL—an immersive learning experience that enlivens familiar and respected course content with media interactives and assessments. Designed for the way today's students read, think, and learn, REVEL empowers educators to increase engagement in the course, to better connect with students, and to break through to learning reimagined.

## Writing Space

Better writers make great learners—who perform better in their courses. To help you develop and assess concept mastery and critical thinking through writing, we created Writing Space.

It's a single place to create, track, and grade writing assignments, provide writing resources, and exchange meaningful, personalized feedback with students, quickly and easily, including auto-scoring for practice writing prompts. Plus, Writing Space has integrated access to Turnitin, the global leader in plagiarism prevention.

## **Learning Catalytics**

Learning Catalytics is a "bring your own device" student engagement, assessment, and classroom intelligence system. It allows instructors to engage students in class with real-time diagnostics. Students can use any modern, webenabled device (smartphone, tablet, or laptop) to access it.

#### Instructor's Manual

The Instructor's Manual (ISBN 0134403045) includes suggestions for preparing for the course, sample syllabi, and current trends and strategies for successful teaching. Each chapter offers integrated teaching outlines, lists the key terms for each chapter for quick reference, and provides an extensive bank of lecture launchers, handouts, and activities, as well as suggestions for integrating third-party videos and web resources. The electronic format features click-and-view hotlinks that allow instructors to quickly review or print any resource from a particular chapter. This resource saves prep work and helps maximize classroom time. Chapter and module quiz answers can also be found in the Instructor's Manual.

Standard Lecture PowerPoint Slides (ISBN 0134377850) are available online at http://www.pearsonhighered.com/irc, with a more traditional format with excerpts of the text material, photos, and artwork.

#### Create a Custom Text

For courses with enrollments of at least 25 students, instructors can create their own textbook by combining chapters from best-selling Pearson textbooks or reading selections in a customized sequence. To begin building a custom text, visit www.pearsoncustomlibrary.com.

Instructors can also work with a dedicated Pearson Custom editor to create the ideal text—publishing original content or mixing and matching Pearson content. Contact a Pearson publisher's representative to get started.

#### **ASSESSMENT**

Instructors consistently tell us that assessing student progress is a critical component to their course and one of the most time-consuming tasks. Vetted, good-quality, easy-to-use assessment tools are essential. We have been listening and we have responded by creating the absolutely best assessment content available on the market today.

#### Test Bank

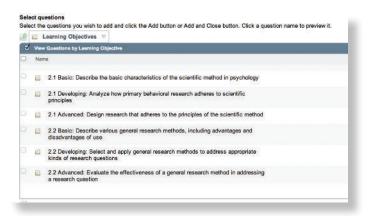

The Test Bank (ISBN 0134377842) contains more than 3,000 questions, many of which were class-tested in multiple classes at both 2-year and 4-year institutions across the country prior to publication. Item analysis is provided for all class-tested items. All questions have been thoroughly reviewed and analyzed line-by-line by a development editor and a copy editor to ensure clarity, accuracy, and delivery of the highest-quality assessment tool. All conceptual and applied multiple-choice questions include rationales for each correct answer and the key distracter. The item analysis helps instructors create balanced tests, while the rationales serve both as an added guarantee of quality and as a time-saver when students challenge the keyed answer for a specific item. The Test Bank includes a two-page Total Assessment Guide, an easy-to-reference grid that organizes all test items by learning objective and question type.

empiricism and determinism are applied to human behavior	Short	Answer	- 1			

In addition to this high-quality Test Bank, a second bank containing more than 2,000 questions is available for instructors looking for more variation. It has also been class-tested, with item analysis available for each question.

The Test Bank also comes with Pearson MyTest, a powerful assessment generation program that helps instructors easily create and print quizzes and exams. Questions and tests can be authored online, providing instructors with the ultimate in flexibility and the ability to efficiently manage assessments wherever and whenever they want. Instructors can easily access existing questions and then edit, create, and store them using simple drag-and-drop and Word-like controls. The data for each question identifies its difficulty level and the text page number where the relevant content appears. In addition, each question maps to the text's major section and Learning Objective. For more information, go to www.PearsonMyTest.com.

BlackBoard Test Item File and WebCT Test Item File: For instructors who need only the test item file for their learning management system, we offer the complete test item file in BlackBoard and WebCT format. Go to the Instructor's Resource Center at http://www.pearsonhighered.com/irc.

#### **APA** Assessments

A unique bank of assessment items allows instructors to assess student progress against the American Psychological Association's Learning Goals and Outcomes. These assessments have been keyed to the APA's latest progressive Learning Outcomes (basic, developing, advanced).

For access to all instructor supplements for *Psychological Science: Modeling Scientific Literacy*, go to www.pearsonhigh ered.com/irc and follow the directions to register (or log in if you already have a Pearson user name and password). Once you have registered and your status as an instructor is verified, you will be emailed a log-in name and password. Use your log-in name and password to access the catalog.

Click on the "online catalog" link, click on "psychology" and then "introductory psychology," and finally select the Krause/Corts, *Psychological Science* text. Under the description of each supplement is a link that allows you to download and save the supplement to your desktop.

You can also request hard copies of the supplements through your Pearson sales representative. If you do not know your sales representative, go to www.pearsonhigh ered.com/replocator and follow the directions to identify him or her.

For technical support for any of your Pearson products, you and your students can contact http://247.pearsoned.com.

# **Development Story**

Psychological Science reflects the countless hours and extraordinary efforts of a team of authors, editors, and reviewers that shared a vision for not only a unique introductory psychology textbook, but also the most comprehensive and integrated supplements program on the market. Over 300 manuscript reviewers provided invaluable feedback for making the text as accessible and relevant to students as possible. Each chapter was also reviewed by a panel of subject matter experts to ensure accuracy and currency. Over 200

focus group participants helped guide every aspect of the program, from content coverage to the art style and design, to the configuration of the supplements. Over 200 students class tested the full manuscript and Test Bank to ensure the best content possible and over 500 students compared the manuscript to their current textbooks and provided suggestions for improving the prose and design. We thank everyone who participated in ways great and small, and hope that you are as pleased with the finished product as we are!

# Acknowledgments

The fact that there are two names on the cover is quite an understatement. If you were to look behind the scenes, you would find scores of people working a variety of roles to see this project to completion. Many of those individuals lead the team at Pearson Education including our Executive Editor, Erin Mitchell and our Program Manager, Reena Dalal who has proven both incredibly knowledgeable and completely unflappable. To our diligent Developmental Editors, Lai Moy and Mary Piper Hansen, we thank you for your guidance and patience. A major thank you to Sherry Lewis, project manager, for vigilantly keeping us on track from beginning to end. These are just a few of the names you will find in the credits, but only the tip of the iceberg. In addition to our friends in publishing, we have received steadfast

support from those we see everyday. This ranges from the colleagues in our departments to those who matter most—our families. We are particularly grateful for our children and spouses who have been gracious enough to share our time with such a time-intensive project. Finally, no textbook could purport to represent as vast a discipline as psychology without the expertise of a wide range of professionals. Dozens of reviewers provided this expertise by suggesting recently published research and ways of presenting information to students. Thanks to our reviewers for their past contributions and we hope that you, as well as those who are new to the project, will continue to offer suggestions or comments by writing to Mark Krause (krausema@sou.edu) and Daniel Corts (danielcorts@augustana.edu).

# **\**

## **Learning Objectives**

- **1.1a** Know . . . the key terminology of the scientific method.
- **1.1b** Understand . . . the steps of the scientific method.
- **1.1c** Understand . . . the concept of scientific literacy.

Her (2013) is not your typical love story. Theodore (played by Joaquin Phoenix) falls in love with Samantha (Scarlett Johansson). They are perfect for each other, it would seem. But here is the conflict: Samantha is not a person; she is an artificial intelligence software designed to behave less like a machine and more like a living, breathing human being. Although the plot of Her is based on science fiction, encountering a "being" like Samantha may be closer to reality than you think. Ellie, for instance, is a computer-generated avatar developed by scientists at the University of Southern California. Ellie is designed to carry on conversations with you—sometimes seemingly meaningful ones. By detecting subtle changes in your facial expressions, speech patterns, and posture, Ellie is

- **1.1d** Apply . . . the biopsychosocial model to behavior.
- **1.1e** Apply . . . the steps in critical thinking.
- **1.1f** Analyze . . . the use of the term *scientific theory*.

able to respond with vocal changes and gestures as a caring human would. If you feel a bit down, you will find that Ellie's expression may change as she listens; her voice may soften and she may even mention that you seem a bit upset. Many who have spoken with Ellie have been surprised that a technology comprising a series of algorithms can seem so empathetic.

So what do these virtual women have to do with your psychology course? The nonfictional Ellie demonstrates how scientific inquiry can reveal some pretty reliable facts about how people think, feel, and behave. Her fictional counterpart Samantha entertains by showing us how fascinating these thoughts and feelings can be. We hope you will learn both in this chapter.

Psychology is a vast discipline; in fact, we might do better to consider it to be a collection of disciplines, composed of many overlapping fields of study. Two unifying qualities allow us to group all these fields into the single category of *psychological science*. First, psychology involves the study of behavior that, broadly defined, can include perceptions, thoughts, and emotions. Second, psychologists employ the *scientific method* in their work. On these grounds, we can define **psychology** as the scientific study of behavior, thought, and experience.

#### The Scientific Method

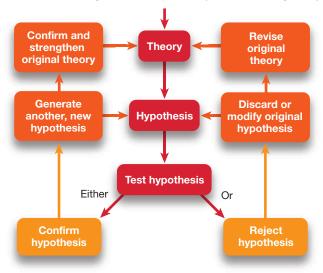

What exactly does it mean to be a scientist? A person who haphazardly combines chemicals in test tubes may look like a chemist; a person who dissects a frog just to see its organs may appear to be a biologist—but neither is engaged in science. For a specific type of activity to be considered *scientific* or a field of study to be considered a *science*, application of the scientific method is a must. The **scientific method** is a way of learning about the world through collecting observations, proposing explanations for the observations, developing theories to explain them, and using the theories to make predictions about future occurrences or behaviors. It revolves around the concepts of hypothesis and theory and how they interact to produce a discipline-based body of knowledge (see Figure 1.1).

#### HYPOTHESES: MAKING PREDICTIONS A hypothesis

(plural: hypotheses) is a testable prediction about processes that can be observed and measured. By testable, we mean that observations and measurements can be shown whether the prediction was correct or, equally important, whether it

Figure 1.1 The Scientific Method

Scientists use theories to generate hypotheses. Once tested, hypotheses are either confirmed or rejected. Confirmed hypotheses lead to new ones and strengthen theories. Rejected hypotheses are revised and tested again, and can potentially alter an existing theory.

"All swans are white" is a falsifiable statement. A swan that is not colored white will falsify it. Falsification is a critical component of scientific hypotheses and theories.

was false—a quality known as *falsifiability*. People claiming to be scientific regularly ignore falsifiability. Imagine a horoscope reads, "It's time for you to keep quiet and postpone important calls or e-mails." That is not really a testable prediction for a number of reasons, including the fact that it does not describe a specific consequence or a time frame in which a problem might arise. Therefore, if you did make that important call, it would be impossible to show the prediction was false. In contrast, a good scientific hypothesis is stated in more precise, and publicly relevant, terms, such as the following:

People become less likely to help a stranger if there are others around.

Cigarette smoking causes cancer.

Exercise relieves depression.

Unlike the astrologer's prediction, each of these hypotheses can be supported or rejected through scientific testing. Astrology is an easy target for criticism. We bring it up only because it provides an opportunity to clarify what a scientific hypothesis is and also to highlight a key difference between science and **pseudoscience**, which refers to ideas that are presented as science but do not actually use basic principles of scientific thinking or procedure. Alarmingly, approximately one in four Americans believes astrology has at least some scientific basis despite a total lack of evidence or support from trained scientists (National Science Foundation, 2010).

**EXPLAINING PHENOMENA** Hypotheses are essential to creating and refining scientific theories. A **theory** is a well-tested explanation that combines a range of observations into a coherent whole. Figure 1.1 shows how hypothesis testing eventually leads back to the theory from which it was based. Theories are built from hypotheses that are repeatedly tested and confirmed; in turn, good theories eventually become accepted explanations of behavior

or other natural phenomena. Similar to hypotheses, an essential quality of scientific theories is that they are *falsifiable*; like hypotheses, they can be proved false with new evidence. As Figure 1.1 shows, falsifying a theory means that it either needs to be modified to account for new findings, or in some cases, replaced by an entirely new theory. In this way, science becomes self-correcting; bad ideas typically do not last long before being discovered and replaced.

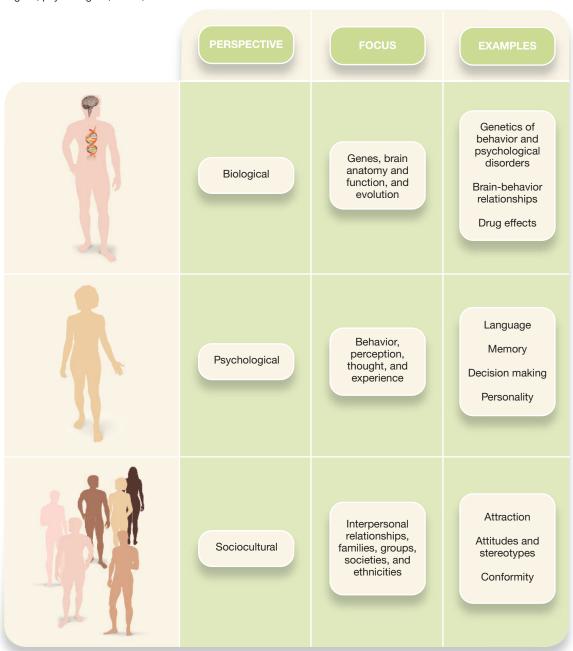

The scientific term *theory* is specific and essential to understanding how explanations differ from common

sense. Make sure that as you read this text you keep in mind *scientific* theory, rather than these common misusages:

- Theories are not the same thing as opinions or beliefs. Yes, it is certainly true that everyone is entitled to his or her own opinions. But the phrase "That's just your theory" is neither the scientific meaning of "theory," nor a valid scientific argument.
- All theories are not equally plausible. Groups of scientists might adopt different theories for explaining the same phenomenon. For example, several

Figure 1.2 The Biopsychosocial Model

Psychologists view behavior from multiple perspectives. A full understanding of human behavior comes from analyzing biological, psychological, social, and cultural factors.

theories have been proposed to explain why people become depressed. This does not mean that all are equally valid. There are good theories, and there are not-so-good theories; the good ones generate successful hypotheses as shown in Figure 1.1.

The quality of a theory is not evaluated by the number of people who believe it to be true. According to a 2013 Pew Research Center Survey, only one third of Americans believe in the theory of evolution by natural selection, despite the fact that it is the most plausible, rigorously tested theory of biological change and diversity.

Testing hypotheses and constructing theories are both part of all sciences. In addition, each science, including psychology, has its own unique way of approaching its subject matter. As the study of behavior, thought, and experience, psychology examines the individual as a product of multiple influences, including biological, psychological, and social factors.

THE BIOPSYCHOSOCIAL MODEL Defining psychology as the scientific study of behavior, thought, and experience may sound pretty straightforward, but thinking and behaving are complex subjects with complex explanations. One psychologist might study a single type of cell in the nervous system, whereas another might examine the cultural customs and beliefs that shape daily life for millions of people—all this to explain the same overarching question: Why do we behave the way we do?

Because our thoughts and behaviors have multiple influences, psychologists adopt multiple perspectives to understand them. The **biopsychosocial model** *is a means of explaining behavior as a product of biological, psychological, and sociocultural factors* (see Figure 1.2). Biological influences on our behavior include brain structures, hormones, and drug effects. On the other end of the spectrum, your family, peers, and immediate social situation also determine how you think, feel, and behave, as do beliefs about social characterisitcs such as ethnicity, gender, or socioeconomic status. These influences constitute the sociocultural part of the model. In between biology and culture, we can examine how a person's thoughts, experiences, emotions, and personality constitute his or her psychological makeup.

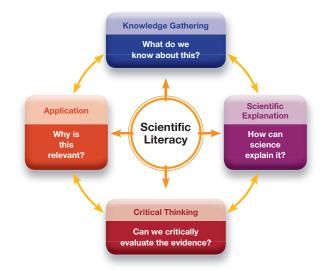

The biopsychosocial model is a reminder that behavior can be fully explained only if multiple perspectives are incorporated.

## **Building Scientific Literacy**

A major aim of this text is to help students develop scientific literacy, which is the ability to understand, analyze, and apply scientific information. Our focal topic is psychology, but these same skills are applicable to other

#### Figure 1.3 A Model of Scientific Literacy

Scientific literacy involves four different skills: gathering knowledge about the world, explaining it using scientific terms and concepts, thinking critically, and applying this knowledge to relevant, real-world situations.

scientific fields. As shown in Figure 1.3, our model of scientific literacy reveals several key components, starting with the ability to learn new information, new terminology, and concepts. However, knowledge of terminology alone does not make one scientifically literate; one must also be able to provide explanations that incorporate the scientific terms and concepts of the discipline one is studying (in this case, psychology). Being scientifically literate means being able to read and interpret new terminology, and knowing when and where to go to find out more. It also means being able to apply this ability to real-world situations and to use one's critical thinking skills to evaluate information and claims.

#### **Working the Scientific Literacy Model**

#### How We Learn and Remember

To give you a chance to develop scientific literacy skills, we will revisit this model regularly and apply its four components to a specific psychological topic—a process we call working the model. We can demonstrate this process with a topic that is familiar to many: using flashcards to study vocabulary terms.

# What do we know about studying with flashcards?

Many college courses require that you learn key-term definitions and factual information such as dates, and students often study with flashcards to master this information. Most students prefer what is called massing—they break up a large pile of cards into smaller groups and move through each mass of cards separately. Another approach is *spacing*—leaving the cards in one big stack and moving through them one at a time. In contrast to massing, spacing means more time passes between each card and more new terms are introduced before any specific card repeats itself. The larger the deck, the more spacing there is before returning to the first card. Most students prefer the massing technique because it seems to allow them to master words more quickly. However, science shows that the two are not equally effective, and that spacing is generally the better of the two.

### How can science explain this difference?

To find out which study method works best, psychologist Nate Kornell (2009) conducted an experiment in which 20 student volunteers agreed to study according to his instructions. Students studied one list of words with massing (four sets of five cards each) and another list with spacing (one set of 20 words). As shown in Figure 1.4, the volunteers studied each word four times, regardless of study method. At the end of the study period, Kornell administered a memory test and discovered that the volunteers could remember more words from the spaced condition than the massed condition. Interestingly, almost all students still preferred massing.

### Can we critically evaluate this conclusion?

There is no such thing as a perfect study; no single experiment will fully answer scientific questions about studying with flashcards or any other topic. Although it is the researcher's job to conduct the best studies possible, it is up to you, the reader, to think critically about them. We provide advice on critical thinking later in this chapter, and once you read Chapter 2, you will be better prepared to assess the quality of the research. For now, start by asking yourself questions about the outcome: Why do students prefer the less effective method? You should think about ways in which this may or may not apply to other situations: Does spacing work better for other types of studying, like learning to solve math problems? You should notice that being critical means asking for limitations and shortcomings without being overly emotional or hostile. This prevents us from wholeheartedly accepting faulty claims, but we should not hastily dismiss any single study either. Instead, we give time for researchers to build evidence with additional studies.

### How is this finding relevant?

Ideally, you will be inspired to apply the findings from Kornell's experiment to your own experiences as a student—whether studying for your psychology or other courses. But to really make use of spacing, you might have to convince yourself to trust the data, especially if you are like the students in Kornell's study and find yourself preferring the massing technique, despite the evidence that more strongly supports the efficacy of spacing!

Keep in mind there is still much to learn about "working the model": The next section focuses on critical thinking skills and how to use them; Chapter 2 walks you through the specific methods for conducting and evaluating scientific research. You will get a chance to "work" the scientific literacy model again in Chapter 2, and then again in the remaining chapters.

### Critical Thinking, Curiosity, and a Dose of Healthy Skepticism

On page 5, as shown in the scientific literacy model, critical thinking is an important element of scientific literacy. Critical thinking involves intentionally analyzing and evaluating beliefs, claims, or judgments. Psychologists often do this by assessing research in terms of how it relates to theory and how well it follows scientific principles.

### Figure 1.4 Massed Versus Spaced Practice

In both conditions of Kornell's experiment, volunteers studied each vocabulary word four times. In the massed condition, shown at left, the individual cards were studied closer together whereas in the spaced condition, at right, they were studied further apart. Spaced learning results in better memory for vocabulary terms.

You have a total of 20 terms to learn.

Massing: Studying a deck of five cards four times in a row. This masses study for an individual card, such as card A in the drawing above.

You have a total of 20 terms to learn.

Spacing: Leaving all 20 cards in one stack and studying the whole deck four times in a row. This spaces the studying for each card, such as card A in the drawing above. However, in both conditions, card A will be studied the same number of times (four).

As such, critical thinking is something you develop and practice rather than something with which you are born (Halpern, 1996).

In addition to analytical and evaluative skills, critical thinking requires a certain set of attitudes or dispositions, namely curiosity, skepticism, and self-reflection. As psychologists, we are always *curious*. We ask questions about all kinds of behaviors, not just the unusual or problematic, which many of us tend to do, but also about everyday activities and experiences (*How do we remember where we left our car keys?*).

We also approach matters with cautious and healthy skepticism. Because we are constantly being told about products that will radically improve our lives or about political positions that are supposedly in everyone's best interests, it is important to raise questions. Being skeptical can be challenging, especially when a product or campaign promise fits our assumptions of the truth or what we hope to be the truth—eventually, though, we have to challenge our own assumptions, even if it risks being proved wrong. Consider again Kornell's research on flashcards: Students overwhelmingly prefer massing, so you may assume massing works best; but if you challenge this assumption, you may actually find a technique that works better. Ultimately, curiosity and skepticism lead us to be reflective. In other words, they help us to reconsider what we think we know, to understand what we know, and to explore why we believe what we believe. Sometimes, the best outcome is to understand what we cannot be certain of, and to tolerate ambiguity when the evidence is inconclusive.

**KEY PRACTICES TO CRITICAL THINKING** Now that you have an idea of what critical thinking entails, it is time to learn the skills and put them to use. Researchers have identified six key practices of a critical thinker:

- 1. Be curious. Look for opportunities to ask questions, even when they are not obvious. Here are two ways to approach curiosity. First, rather than wait until something goes wrong to be curious (Why did he develop depression?), ask questions while things are going well (How did he succeed in the face of all that hardship?). Second, watch out for narrow-minded questions that already presume to have an answer (Why are they all criminals? This question assumes knowledge of "they.") Instead ask open and objective questions (Is that group more likely to engage in crime? If so, why?). Remember that most aspects of behavior are complex; there is usually no single right answer to a question, but rather a complex set of answers.
- **2. Examine the evidence.** Examining the evidence is key to science and critical thinking. Bear in mind that common sense is not evidence, and in fact, it will often lead you astray. Therefore, you should look for evidence that is reliable, objective, and relevant. You

- will be even better equipped to do this after reading Chapter 2, which focuses on scientific processes.
- 3. Examine assumptions and biases. Assumptions and biases too quickly lead us to accept claims that support our expectations and to discount those that do not. Recall that in Kornell's flashcard experiment, the majority of his volunteers preferred massing. We have found that students in our own classes also prefer massing, and as such, they too quickly discount Kornell's rather strong evidence that spacing is better. Fortunately, this particular example does not have severe consequences. However, at their worst, biases and conflicts of interest can lead people to willfully mislead others, sometimes even with fabricated data and claims that they know are not true.
- Avoid overly emotional thinking. Emotions can tell us what we value, but they do not always help us make critical decisions. By all means, emotions should guide decisions about a relationship, career, and so on. However, emotions can lead to some wrong answers, which, at their worst, can have grave consequences. For example, many young parents have opted not to vaccinate their children out of a fear that vaccines may lead to autism. This emotional decision ignores the fact that there is no credible scientific evidence for this threat, and in fact, the most influential medical study to support a purported vaccine-autism link was eventually exposed as a fraud and retracted by the research journal that published it (Godlee, Smith, & Marcovitch, 2011). Critical thinkers acknowledge their emotions, but they carefully discern the situations when emotional-based decisions may not be appropriate.
- 5. Tolerate ambiguity. Most complex issues do not have clear-cut answers, but they do have lots of *ifs, buts,* and *it depends*. For example, for many years the medical community advised the public to avoid eating fats based on the evidence that fats were associated with weight gain and heart disease. However, the same scientific community now encourages us to include certain fats, such as those that come from olive oil or avocados. Although this change seems contradictory, ongoing research will sometimes lead to changes in prior beliefs. This case is just one among many where the apparent contradiction includes an "if." In other words, fats are viewed more favorably, but only *if* they are rich in substances such as omega-3 acids.
- **6. Consider alternative viewpoints.** Finally, make sure you are open to alternative viewpoints. This does not mean that everyone's opinion is equally correct, but you can often learn from the perspective of others. You may even discover that emotions, assumptions, and biases have been affecting your own thinking without your awareness, or that others have better evidence than you do!

### Table 1.1 Critical Thinking

### Practice applying critical thinking skills to the scenario:

Magic Mileage is a high-tech fuel additive that actually increases the distance you can drive for every gallon by 20%, although costing only a fraction of the gasoline itself!! Wouldn't you like to cut your fuel expenses by one-fifth? Magic Mileage is a blend of complex engine-cleaning agents and patented "octane-booster" that not only packs in extra miles per gallon but also leaves your engine cleaner and running smooth while reducing emissions!

- 1. How might this appeal lead to overly emotional thinking?
- 2. Can you identify assumptions or biases the manufacturer might have?
- 3. Do you have enough evidence to make a judgment about this product?

These six practices will help you to develop critical thinking habits and skills. To further hone these habits and skills, also consider what does not constitute critical thinking. Critical thinking is neither a belief nor a faith, nor is it meant to make everyone arrive at the same answer. In fact, complex issues often remain ambiguous, and a plausible answer may not always be possible. Although critical thinking means respecting others' viewpoints, the nature of the scientific method may lead you to discover that some of those ideas are incorrect. Critical thinking does not mean being negatively or arbitrarily critical; it means intentionally examining knowledge and beliefs, as well as how conclusions about them are obtained. It also means carefully examining the sources of information. You can practice applying critical thinking to the scenario in Table 1.1.

### JOURNAL PROMPT

Critical Thinking: What is a common belief people tend to have in which critical thinking is especially lacking? Describe the belief and explain why you think people hold it.

CRITICAL THINKING ABOUT SOURCES Not all sources of information are equal and trustworthy. Therefore, it is important that you pay especial attention to the sources' purpose, openness, accuracy, and comprehensiveness before, during, and after you read or research information.

• Purpose: Make sure you can identify the purpose of the article you are reading. Obviously, this will help you establish whether it is relevant to your needs, but it will also help with other elements of critical thinking, such as determining bias. For example, imagine you are interested in dining out at a new restaurant. If you are counting your calories (purpose), you will likely examine fact-based data about the calorie value of each entree (source), but if you are wondering whether you will enjoy the food (purpose), you will more likely rely on opinion-based reviews (source). You would not read a rave review to find out the calorie value of the entrees because, chances are, the information you find will be biased, inaccurate, or irrelevant. There are parallels to this example in all sorts of domains, from

buying a new car to deciding how to be a better parent. When considering the relationship between purpose and source, ask yourself:

- Is this an opinion piece (e.g., an editorial or a campaign statement)?
- Is this a straightforward report of facts (news) or description (e.g., encyclopedia entry)?
- Is this an advertisement?
- Bias and Openness: Determine whether the source has a social or political agenda, or perhaps financial motives for presenting information in a certain way. For example, if you have encountered a YouTube video highlighting the terrible conditions endured by factory-raised pigs. You watch pigs being kicked, shoved into tiny pens, or denied fresh water. You would not be surprised to discover that an animal rights group produced it, but you would probably be shocked if it were created by an association of hog farmers. It is no surprise that groups with specific agendas and interests will produce media that suit their needs rather than present and assess all sides to the story. Knowing this, you should always ask yourself:
  - Who are the publishers, advertisers, and other supporters of this source? What do these groups stand to gain when the source presents the information?
  - Are multiple opinions or options represented, or should they be?
  - What is being left out?
  - Does the source appear thoughtful, or is there extensive use of exaggeration, sweeping generalizations, or emotional language?
- Accuracy and credibility: Responsibly written articles present accurate and precise information that can be traced back to credible sources. Imagine you encounter an article warning people of the dangers of marijuana on memory and reasoning skills, but you notice that the author has no background in drug research and only cites anecdotes rather than scientific evidence. You would be wise to disregard that article and instead look for a source written by someone with an appropriate background and provides verifiable data to support the opinions. When considering the accuracy and credibility of a source, ask yourself:
  - Are the authors listed?
  - Are claims supported with citations, footnotes, or references?
  - Is it up to date?
  - Do multiple sources agree? (Make sure they are not citing the same original source or sponsored by the same ads or organizations.)
  - If someone is cited as an authority, are they still providing sound evidence? Are they speaking within their realm of expertise?

# Myths in Mind

### Abducted by Aliens!

Independent reports of alien abductions often resemble events and characters depicted in science fiction movies.

Occasionally we hear claims of alien abductions, ghost sightings, and other paranormal activity. Countless television shows and movies, both fictional and documentary, reinforce the idea that these events can and do occur. Alien abductions are often the most complicated and far-fetched stories, yet many people can provide extremely detailed accounts of being

kidnapped and examined. So what should we believe about alien abductions?

Scientific and critical thinking involves the use of the principle of parsimony, which means that the simplest of all competing explanations (the most "parsimonious") of a phenomenon should be the one we accept. Is there a simpler explanation for alien abductions? Probably so. First, historical reports of abductions typically spike just after the release of science fiction movies featuring space aliens. Details of the reports often follow specific details seen in these movies (Clancy, 2005). Second, people who claim to have been abducted are likely to experience sleep paralysis (waking up and becoming aware of being unable to move—a temporary state that is not unusual) and hallucinations while in the paralyzed state (McNally et al., 2004). Finally, people who report being abducted tend to fantasize more than the average person and they also have more false memories (vivid and convincing memories about events that did not happen; Lynn & Kirsch, 1996). Taken together, these lines of research lead to a plausible explanation: abductions could be false memories incorporating elements of media with the experience of sleep paralysis; all of these events are easily observable. In contrast, finding physical evidence of aliens is not. Following the principle of parsimony typically leads to real, though sometimes less spectacular, answers.

# **Module 1.1** Summary

# **1.1a** Know... the key terminology of the scientific method:

biopsychosocial model critical thinking hypothesis pseudoscience psychology scientific literacy scientific method theory

### **1.1b** Understand . . . the steps of the scientific method.

The basic model in Figure 1.1 guides us through the steps of the scientific method. Scientific theories generate hypotheses, which are specific and testable predictions. If a hypothesis is confirmed, new hypotheses may stem from it, and the original theory receives added support. If a hypothesis is rejected, the original hypothesis may be modified and retested, or the original theory may be modified or rejected.

#### **1.1c** Understand . . . the concept of scientific literacy.

Scientific literacy refers to the process of how we think about and understand scientific information. The model for scientific literacy was summarized in Figure 1.2. Working the model involves answering a set of questions:

- What do we know about a phenomenon?
- How can science explain it?
- Can we critically evaluate the evidence?
- Why is this relevant?

You will see this model applied to concepts in each chapter and module of this text. This includes gathering knowledge, explaining phenomena in scientific terms, engaging in critical thinking, and knowing how to apply and use your knowledge.

### **1.1d** Apply... the biopsychosocial model to behavior.

This is a model we will use throughout the text. As you consider each topic, think about how biological factors (e.g., the brain and genetics) are influential. Also consider how

psychological factors such as thinking, learning, emotion, and memory are relevant. Social and cultural factors complete the model. These three interacting factors influence our behavior.

### **1.1e** Apply... the steps in critical thinking.

To be useful, critical thinking is not just a concept to memorize but rather a skill to use and apply. Remember, critical thinking involves (1) being curious, (2) evaluating the evidence, (3) examining assumptions and biases, (4) avoiding emotional thinking, (5) tolerating ambiguity, and (6) considering alternative viewpoints. The activity in Table 1.1 was designed to help you apply some critical thinking. Here are the answers we came up with.

### Apply Activity: Table 1.1, p. 08

 The appeals to your wallet and to your environmental conscience sound great, but it might be too good to be true!

- The manufacturer is trying to make money. That does not make the company evil, but it might lead its marketing staff to exaggerate the benefits offered by its products.
- **3.** We do not have any evidence that the product works, just the manufacturer's claim. Until you find the evidence, you must tolerate ambiguity; you cannot say if it is effective or not.

### **1.1f** Analyze . . . the use of the term *scientific theory*.

The term *theory* is often used very casually in the English language, sometimes synonymously with *opinion*. Thus, it is important to analyze the scientific meaning of the term and contrast it with the common-use alternatives. A scientific theory is an explanation for a broad range of observations, integrating numerous findings into a coherent whole. Remember, theories are not the same thing as opinions or beliefs, all theories are not equally plausible, and strange as it may sound, a measure of a good scientific theory is not determined by the number of people who believe it to be true.

## **Module 1.1 Quiz**

Know . . .

1.	A testable prediction about processes that can be observed
	and measured is referred to as a(n)

- A. theory
- B. hypothesis
- C. opinion
- D. hunch

### Understand . . .

- 2. A theory or prediction is falsifiable if:
  - A. it has been proven false.
  - **B.** it is impossible to test.
  - **C.** there can be evidence for it or against it.
  - **D.** if and only if it comes from pseudoscience.
- 3. Scientific literacy does not include \_\_\_\_\_
  - A. gathering knowledge
  - B. accepting common-sense explanations
  - C. critical thinking
  - D. applying scientific information to everyday problems

### Apply . . .

- 4. Huang is considering whether to take a cholesterol-reducing medicine that has been recommended by his physician, so he inquires about its effectiveness and safety. His physician explains that the government agency that oversees medications—the Food and Drug Administration (FDA)—has approved the medication after dozens of scientific studies had been conducted on their usefulness and safety. Which aspect of critical thinking does this best represent?
  - A. Huang is examining the nature and source of the evidence.
  - B. Huang is simply curious.
  - **C.** Huang is not considering alternative viewpoints.
  - **D.** Huang is avoiding overly emotional thinking.

### Analyze . . .

- 5. The scientific meaning of the word theory is different from how it is most often used in nonscientific language because
  - **A.** it describes an explanation based on a variety of welltested, objective observations rather than speculation.
  - **B.** it simply reflects the opinions of a particular scientist instead of the facts.
  - C. it is phrased in such a way that it cannot be proven incorrect.
  - D. it can be proven.

# Module 1.2 How Psychology Became a Science

# Learning Objectives

- **1.2a** Know . . . the key terminology of psychology's history.
- **1.2b** Understand . . . how various philosophical ideas and scientific fields became major influences on psychology.

Domenico Mattiello garnered a great deal of respect and admiration in more than 30 years as a pediatrician, but it was all lost the instant investigators charged him with lewd conduct, including making sexual advances toward young children in his care. In his trial, lawyers did not deny the charges, but argued Mattiello's defense with medical records and brain scans. There was no doubt that he suffered a large and growing brain tumor or that the tumor was associated with changes in personality and behavior. So the legal question was raised: Did Mattiello commit the crimes or was the tumor guilty?

The premise of this legal defense should be familiar. Most judicial systems address questions about competence to stand trial, the ability to discern right from wrong, and other

- **1.2c** Apply . . . your knowledge to distinguish among the different specializations and schools of thought in psychology.
- **1.2d** Analyze . . . how the philosophical ideas of empiricism and determinism are applied to human behavior.

inherently psychological questions. Underlying this legal question is the concept of free will—a topic that has been fundamental to philosophy for thousands of years. Increasingly, data from psychological research is used to influence how judges and jurors wrestle with the tough cases. It is interesting to note that although brain-based explanations are frequently useful, they often have little influence in people's assumptions about free will in everyday life (Nahamis, Sheperd, & Reuter, 2014). In this module, we will examine how many fascinating topics originating in ancient philosophy have developed into scientific questions explored by modern scientific techniques. These age-old topics, along with many new ones, make up psychological science today.

Modern psychology is built on many ideas and investigative techniques that have emerged over centuries of scholarly thought. In this module we put psychological questions and our attempts to answer them into historical context and see how these questions have influenced the current field of psychology.

# Psychology's Philosophical and Scientific Origins

Science is more than a body of facts to memorize or a set of subjects to study. Science is actually a philosophy of knowledge that stems from two fundamental beliefs: empiricism and determinism.

Empiricism is a philosophical tenet that knowledge comes through experience. In everyday language, you might hear the phrase "Seeing is believing," but in the scientific sense, empiricism means that knowledge about the world is based on careful observation, not common sense or speculation. Whatever we see or measure should be observable by anyone else who follows the same methods. In addition, scientific theories must be rational explanations of how the observations fit together. Thus, although the empiricist might say, "Seeing is believing," thinking and reasoning about observations are just as important.

**Determinism** is the belief that events are governed by lawful, cause-and-effect relationships. This is easy enough when we discuss natural laws such as gravity; we probably all agree that if you drop a heavy object, it will fall. But does the lawfulness of nature apply to the way we think and feel? Does it mean that we do not have control over our own actions? This interesting philosophical debate is often referred to as free will versus determinism. Although we certainly feel as if we are in control of our own behaviors that is, we sense that we have free will—there are some compelling reasons (such as Mattiello's brain-based legal defense) to believe that our behaviors are determined. The level of determinism or free will psychologists attribute to humans is certainly debated, and to be a psychologist, you do not have to believe that every single thought, behavior, or experience is determined by natural laws. But psychologists certainly do recognize that behavior is determined by both internal (e.g., genes, brain chemistry) and external (e.g. the presence of others) influences.

Psychological science is both empirical and deterministic. Our understanding of behavior comes from observing what we can see and measure, and behavior is caused by a multitude of factors. However, psychology arrived at this point only in the latter half of the 1800s—much later than the well-established sciences of physics, astronomy, and chemistry. Why did it take psychology so long to become scientific? One of the main reasons is *zeitgeist*, a German word meaning "spirit of the times." **Zeitgeist** *refers to a general set of beliefs of a particular culture at a specific time in* 

history. It can be used to understand why some ideas take off immediately, whereas other perfectly good ideas may go unnoticed for years. The historical timeline of psychology shown in Figure 1.5 reflects the major viewpoints that have become a part of psychology over the past three centuries.

There are several ways zeitgeist may have prevented psychological science from developing alongside physical sciences. For example, philosophers such as Rene Descartes had no problem conceiving of the human body as a natural, lawfully behaving machine (human anatomy could be scientific). However, viewing human reasoning as the result of predictable physical laws was troubling, and many people resisted applying science to thought. Doing so would seem to imply the philosophy of **materialism**: the belief that humans, and other living beings, are composed exclusively of physical matter. Accepting this idea would mean that we are nothing more than complex machines that lack a self-conscious, self-controlling soul. The opposing belief, that there are properties of humans that are not material (a mind or soul separate from the body), is called *dualism*. Therefore, although thinking about the mind and behavior remained philosophical for generations, scientific methods were generating great discoveries in other fields.

INFLUENCES FROM PHYSICS: EXPERIMENTING WITH THE MIND The initial forays into scientific psychology were conducted by physicists and physiologists. One of the earliest explorations was made by Gustav Fechner (1801–1887). As a physicist, Fechner was interested in the natural world of moving objects and energy. These interests turned psychological when he began raising questions about human perception of the physical world. He called this **psychophysics**, the study of the relationship between the physical world and the mental representation of that world.

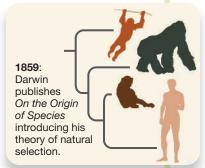

As an example of psychophysical research, imagine you are holding a 1-pound weight in your right hand and a 5-pound weight in your left hand. What if a researcher places a 1/4-pound weight in each hand, resting on top of the weight that is already there? Although both weight he same amount physically—1/4 of a pound—the weight in your right hand will in some sense be psychologically heavier because it is a greater proportion of the original weight. Through psychophysical experiments like these, Fechner developed an equation to precisely calculate the perceived change in weight, and then extended this formula to apply to changes in brightness, loudness, and other perceptual experiences.

INFLUENCES FROM EVOLUTIONARY THEORY: THE ADAPTIVE FUNCTIONS OF BEHAVIOR Around the same time Fechner was doing his experiments, Charles Darwin (1809–1882) was studying the variety of plants and animals around the world. Darwin noticed that animal groups that were isolated from one another often differed

Figure 1.5 Major Events in the History of Psychology

**Late 1700s:** Franz Mesmer develops techniques to treat mental illness, including the use of hypnosis.

**Around 1850**: Gustav Fechner pioneers the study of psychophysics.

**1861:** Physician Paul Broca discovers a brain area associated with the production of speech, now known as Broca's area, establishing that regions of the brain are specialized to serve different functions.

**1879**: Wilhelm Wundt establishes the first psychological laboratory in Leipzig, Germany, and two years later he establishes the first journal in psychology.

**1883**: G. Stanley Hall establishes his laboratory at Johns Hopkins University in Baltimore—the first psychology laboratory in the United States.

**1880s**: Francis Galton introduces and develops the study of anthropometrics.

**1885**: Hermann Ebbinghaus begins his scientific study of memory.

**1890:** William James, founder of the functionalist approach, publishes *Principles of Psychology*.

**1892**: The American Psychological Association (APA) is established.

**1936:** Kurt Lewin authors *Principles* of *Topological Psychology*, which introduces the social psychological formulation that the behavior of individuals is influenced by their social environment.

**1929:** Psi Chi is founded as the National Honor Society in psychology to recognize and support excellence in academic psychology.

**1913**: John B. Watson writes "Psychology as the Behaviorist Views It," establishing behaviorism as the primary school of thought in American psychology.

1912: Max Wertheimer establishes the field of gestalt psychology.

**1911:** Edward Thorndike demonstrates the basic principles of instrumental learning, forming the basis for the study of operant conditioning.

**1905**: Alfred Binet develops the first intelligence test.

**Early 1900s:** Ivan Pavlov demonstrates the basic principles of classical conditioning.

**1904:** Mary Calkins is elected the first female president of the American Psychological Association.

**1900:** Sigmund Freud writes *The Interpretation of Dreams*, a key book in the development of psychoanalysis.

**1896**: Lightmer Witmer established the first psychological clinic at the University of Pennsylvania.

**1894**: Margaret Washburn is the first female to receive a PhD in psychology.

**1938**: B. F. Skinner writes the *Behavior of Organisms*, which furthers the cause of behaviorism.

**1951**: Carl Rogers writes *Client-Centered Therapy*, which helps establish humanistic psychology.

**1967**: Ulrich Neisser publishes *Cognitive Psychology*, which introduces a major new subfield of psychology.

1971: B. F. Skinner publishes Beyond Freedom and Dignity, stirring controversy over radical behaviorism.

**1978**: Herbert

Simon wins the Nobel Prize in economics for research in cognitive psychology (there is no Nobel Prize dedicated to psychology).

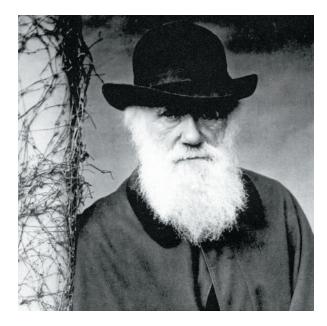

**1988**: Establishment of the American Psychological Society, now known as Association for Psychological Science (APS).

1990s: President George H. W. Bush proclaims the 1990s to be "The Decade of the Brain," and there is unprecedented growth in neuroscience and biological psychology.

**2000:** Eric Kandel, Arvid Carlsson and Paul Greengard win the Nobel Prize for physiology or medicine for their discoveries of the cellular basis of memory.

**2003**: The Human Genome Project is completed.

2013: The American Psychiatric Association publishes the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders*, 52 years after the 1st edition was released.

Charles Darwin proposed the theory of natural selection to explain how evolution works.

by only minor variations in physical features. These variations seemed to fine-tune the species according to the particular environment in which they lived, making them better equipped for survival and reproduction. Darwin's theory of evolution by natural selection was based on his observations that the genetically inherited traits that contribute to survival and reproductive success are more likely to flourish within the breeding population. This theory explains why there is such a diversity of life on Earth.

What does evolution have to do with psychology? As Darwin pointed out in *The Expression of the Emotions in Man* and Animals (1872), behavior is shaped by natural selection, just as physical traits are. Darwin noted that for many species, including humans, survival and reproduction are closely related to an individual's ability to recognize some expressions as threats and others as submission. To Darwin, it appeared that emotional expressions and other behaviors were influenced by natural selection as well. Even before Darwin, humans had selectively bred animals to behave in certain ways (i.e., artificial selection of traits, rather than natural selection). Sheep dogs make good herders, whereas their pit bull cousins do not. Retrievers and pointers are good at hunting with humans, but how long would a toy poodle last in this context? Darwin's recognition that behaviors, like physical traits, are subject to hereditary influences and natural selection was a major contribution to psychology.

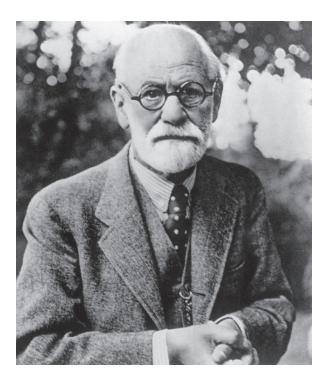

INFLUENCES FROM MEDICINE: DIAGNOSES AND TREATMENTS Medicine contributed a great deal to the biological perspective in psychology, as well as clinical **psychology**, which is the field of psychology that concentrates on the diagnosis and treatment of psychological disorders. One

interesting area of medical study was brain localization, the idea that certain parts of the brain control specific mental abilities and personality characteristics. Physicians noted that when a specific area of the brain was damaged, the correlated function was affected as in these two interesting examples:

- Physician Paul Broca studied a patient named Tan. Tan received this name because it was the only word he could speak, despite the fact that he could hear and understand perfectly well. Broca identified an area of the left side of Tan's brain that was damaged and claimed to have found where speech production was localized; that area of the brain is now known as Broca's area.
- Motivated by Broca's work, Karl Wernicke identified Wernicke's area in 1874. Patients with damage to Wernicke's area could speak in sentences that sounded normal, but with unusual or made-up words. Patients who regained some of their speech later reported that, although they could hear just fine, no speech—not even their own—made sense during the recovery period.

Additional medical influences on psychology came from outside of mainstream practices. Working in Paris, physician Franz Mesmer, believed that prolonged exposure to magnets could redirect the flow of metallic fluids in the body, thereby curing disease and insanity. Although his claim was rejected outright by the medical and scientific communities, some of his patients seemed to be cured after being lulled into a trance. Modern physicians and scientists attribute these cures to belief in the treatment what we now call a placebo effect. This practice also caught the attention of an Austrian physician named Sigmund Freud (1856-1939), who began to use the related concept of hypnosis to treat his own patients. Freud believed hypnosis cured several patients of hysterical paralysis—a condition in which an individual loses feeling and control in a specific body part, despite the lack of any known neurological damage or disease.

Freud's belief in his successes contributed to his theory of psychoanalysis, which is a method of explaining how behavior and personality are influenced by primitive drives and unconscious thought processes. Freud acknowledged that conscious experience includes perceptions, thoughts, and a sense of self. However, he also believed in an unconscious mind driven to fulfill self-serving sexual and aggressive impulses. Freud proposed that because these urges were unconscious, they could exert influence in strange ways, such as restricting the use of a body part (psychosomatic or hysterical paralysis). When a person is hypnotized, dreaming, or perhaps medicated into a trancelike state (Freud had a fondness for cocaine during a period of his career), the psychoanalyst could have direct access into the

Sigmund Freud developed the concept of an unconscious mind and its underlying processes in his theory of psychoanalysis.

individual's unconscious mind. Once Freud gained access, he could attempt to determine and correct any desires or emotions he believed were causing the unconscious to create the psychosomatic conditions.

Although Freud neglected to conduct scientific experiments to test his ideas about human behavior, his legacy can be seen in some key elements of scientific psychology. First, many modern psychologists make inferences about unconscious mental activity, just as Freud had advocated. Second, the use of medical ideas to treat disorders of emotions, thought, and behavior an approach known as the medical model—can be traced to Freud's influence. Third, Freud incorporated evolutionary thinking into his work; he emphasized how physiological needs and urges relating to survival and reproduction can influence our behavior. Finally, Freud placed great emphasis on how early life experiences influence our behavior as adults-a perspective that comes up many times in this text.

THE INFLUENCE OF SOCIAL SCIENCES: MEASURING AND COMPARING HUMANS A third influential force came out of the social sciences of economics, sociology, and anthropology. Sir Francis Galton (1822-1911) combined the mathematical methods of economics with discussions of social class and ethnicity and made them relevant to psychology. Shortly after Galton's cousin, Charles Darwin, introduced his theory of evolution, Galton wondered why intelligence and achievement seemed to run in some families and not in others—particularly those who have

languished in poverty for generations. Is it possible that psychological traits can be inherited? For Galton, yes—it seemed natural that people who succeed in academics and business would inherit psychological traits that lead to high achievement. Galton was convinced by his own family lineage: his cousin Darwin was a great naturalist and his uncle Erasmus was a celebrated physician and writer. Galton himself began to read at age 2. You will see that many of Galton's beliefs and biases are no longer popular today, but several of his key contributions continue to influence research methods in psychology:

- Galton developed a psychological measure of eminence—a combination of ability, morality, and achievement-which he claimed was based on heredity. One observation helped to support this claim: The closer one relative is to another, the more similar are the traits they share. Although eminence is no longer used as a measure, modern psychology continues to emphasize the importance of measuring traits and behaviors and doing so accurately.
- Galton's statistical methods are the foundation of correlation, a mathematical representation of how two variables might go together. For example, wealth and academic achievement go together, as reflected in the calculation of correlation statistics.
- Galton pioneered the study of nature and nurture relationships, the inquiry into how heredity (nature) and environment (nurture) influence behavior and mental processes. He came down decidedly on the nature side, rejecting the likelihood that social conditions influenced eminence. Although we continue to explore nature and nurture, the focus is now on how they interact to produce individual abilities and traits.

Ultimately, Galton wanted his research to improve society—and so he attempted to scientifically justify eugenics, which literally translates as "good genes." He argued that his society—19th-century England should encourage intelligent, talented individuals to have children, whereas criminals, those with disabilities, and other races should be kept out of the English gene pool. Modern psychologists continue to conduct research that they hope will improve society; however, we now understand the benefits of improving the social and educational conditions for children (nurture) and the futility and injustice of eugenics (an extreme view of nature).

Galton originated a lot of the methods and questions found in modern psychology, but you would be hardpressed to find current research arguing for eugenics. Ironically, one of his contributions has been to serve as an example of how not to employ those very same methods. The eugenics movement was based on supporting preexisting beliefs rather than testing their validity and usefulness. Scientists are not perfect now, but definitely more cautious about creating falsifiable hypotheses. Also, remember that critical thinkers are willing to be proven wrong, and they always examine preexisting biases.

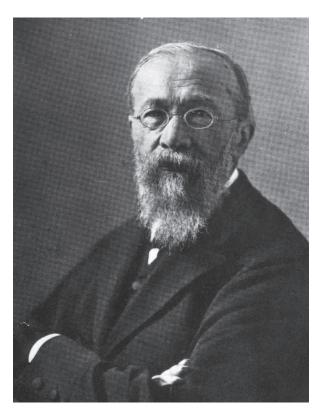

### The Beginnings of Contemporary Psychology

As you now know, before psychology became its own discipline, there were scientists working across different fields who were converging on a study of human behavior. It is possible that physicists could have gone on studying psychophysics, physicians could have continued studying brain injuries, and biologists could have kept studying evolutionary influences on behavior. By modern standards, Darwin, Fechner, and others had produced psychological research, but it was not referred to as such because the field had not yet formed. Nevertheless, progress toward a distinct discipline of psychology was in the works.

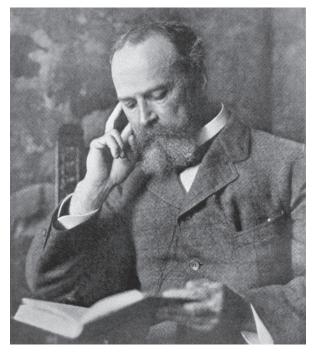

STRUCTURALISM AND FUNCTIONALISM: BEGINNINGS OF PSYCHOLOGY Wilhelm Wundt (1832–1920) is credited with establishing the first psychology laboratory. His primary research method was

introspection (to "look within"), which required a trained volunteer to experience a stimulus and then report each individual sensation he or she could identify. For example, if the volunteer were given a steel ball, he would likely report the sensations of cold, hard, smooth, and heavy. To Wundt, these basic sensations were mental atoms that combined to form the molecules of experience. Wundt also developed reaction time methods as a way of measuring mental effort. In one such study, volunteers watched an apparatus in which two metal balls swung into each other to make a clicking sound. The volunteers required about one-eighth of a second to react to the sound, leading Wundt to conclude that mental activity is not instantaneous, but rather it requires a small amount of effort measured by the amount of time it takes to react. What made Wundt's work distinctly psychological was his focus on measuring mental events and examining how they were affected by his experimental manipulations.

Wundt's student, Edward Titchener, brought the introspection method to the United States and began mapping the structure of human consciousness. Structuralism was an attempt to analyze conscious experience by breaking it down into basic elements and to understand how these elements work together. Titchener chose the term elements deliberately as an analogy with the periodic table in the physical sciences. He believed that mental experiences were made up of a limited number of sensations, which

German scientist Wilhelm Wundt is widely credited as the father of experimental psychology.

William James was a highly influential American psychologist who took a functionalist approach to explaining behavior.

were analogous to elements in physics and chemistry. According to Titchener, different sensations can form and create complex compounds, just like hydrogen and oxygen can combine to form water  $(H_2O)$ .

US scholar William James (1842-1910) authored the first textbook in psychology, The Principles of Psychology, which was published in 1890. In it, James emphasized functionalism, the study of how behavior and thought function in organisms' adaptation to their environments. In contrast to structuralism, which looks for permanent, unchanging elements of thought, functionalism examines how our brains and behaviors have been shaped by the physical and social environment that our ancestors encountered. These ideas can be found today in the field of evolutionary psychology.

Although some of those techniques, such as Wundt's introspection, are no longer used, by the turn of the 20th century, it was clear that the discipline of psychology was here to stay. With that sense of permanence in place, the second generation of psychologists could focus on refining the subject matter and the methods and turning psychology into a widely accepted scientific field.

THE RISE OF BEHAVIORISM Early in the 20th century, biologists became interested in how organisms learn to anticipate their bodily functions. One of the first to do so was Professor Edwin Twitmyer (1873-1943), a US psychologist interested in reflexes. His work involved a contraption with a rubber mallet that would regularly tap the patellar tendon just below the kneecap; this, of course, causes a kicking reflex in most individuals. To make sure his volunteers were not startled by the mallet, the contraption would ring a bell right before the mallet struck the tendon. As is often the case in experiments, the technology failed after a number of these bell-ringing and hammertapping combinations: The machine rang the bell, but the hammer did not come down on the volunteer's knee. But the real surprise was that the volunteer's leg kicked anyway! Because the sound of the bell successfully predicted the hammer, the ringing soon had the effect of the hammer itself, a process now called *classical conditioning*. The study of conditioning would soon become a focus of behaviorism, which is an approach that dominated the first half of the 20th century of US psychology and had a singular focus on studying only observable behavior, with little to no reference to mental events or instincts as possible influences on behavior.

Unfortunately for Twitmyer, his research was coolly received at the American Psychological Association meeting and the credit for discovering classical conditioning typically goes to a Russian physiologist named Ivan Pavlov (1849–1936). Pavlov's Nobel Prize-winning research showed that dogs could learn to salivate to a tone

Ivan Pavlov (on the right) explained classical conditioning through his studies of salivary reflexes in dogs.

if the tone has a history of sounding just before the delivery of food (Module 6.1).

Credit for the rise of behaviorism in the United States typically goes to John B. Watson (1878-1958). As research accumulated on the breadth of behaviors that could be conditioned, Watson began to believe that all behavior could ultimately be explained through conditioning. This emphasis on learning also came with stipulations about what could and could not be studied in psychology. Watson was adamant that only observable changes in the environment and behavior were appropriate for scientific study. Methods such as Wundt's introspection, he said, were too subjective to even consider. And, in stark contrast to Galton's eugenics, Watson believed anything was possible with controlled conditioning:

Give me a dozen healthy infants, well-formed, and my own specified world to bring them up in and I'll guarantee to take any one at random and train him to become any type of specialist I might select-doctor, lawyer, artist, merchant-chief and, yes, even beggar-man and thief, regardless of his talents, penchants, tendencies, abilities, vocations, and race of his ancestors. (Watson, 1930, p. 82)

After an indiscretion involving a female graduate student, Watson lost his university job, but found his new career in advertising. Advertisers at the time assumed they should inform people about the merits of a product. Watson, however, discovered a consumer's knowledge about a product really was not that important, so long as he or she had positive emotions associated with it. Thus, Watson's company developed ads that employed behaviorist principles to form associations between a product's

B.F. Skinner revealed how rewards affect behavior by conducting laboratory studies on animals.

brand image and positive emotions. If Pavlov's dogs could be conditioned to salivate when they heard a tone, what possibilities might there be for conditioning humans in a similar way? Modern advertisers want the logos for their brands of snacks or the trademark signs for their restaurants to bring on a specific craving, and some salivation along the way. We have Watson and his colleagues to thank for this phenomenon.

Taking up the reins from Watson was B. F. Skinner (1904-1990), another behaviorist who had considerable influence over US psychology for several decades. Like Watson, Skinner believed that psychology was the study of behavior and not of the unobservable mind. His approach differed from Watson's and was based on the relatively straightforward observation that organisms repeat behaviors that bring rewards and avoid those that do not. Typically, these studies occurred with animals held in small chambers in which they could manipulate a lever to receive rewards such as food and water. The experimenter would control when rewards were available, and the animal's task was to learn the reward schedule. Though we are clearly different from pigeons in many ways, behaviorists determined that many of the principles in animal learning can apply to humans as well.

Watson's and Skinner's concept of behaviorism met with resistance from many psychologists. If our behavior is controlled by external stimuli and rewards, then this leaves little room for free will. Many of those who resisted believed that humans could rise above their instinctive drives for rewards.

**HUMANISTIC PSYCHOLOGY EMERGES** In response to the deterministic views in behaviorism, psychoanalysis, and eugenics, a new psychological perspective arose in the

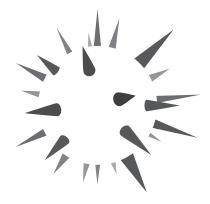

1950s. **Humanistic psychology** focuses on the unique aspects of each individual human, each person's freedom to act, his or her rational thought, and the belief that humans are fundamentally different from other animals. Figures such as Carl Rogers (1902-1987) and Abraham Maslow (1908-1970) focused on the positive aspects of humanity, the meaning of personal experience, and the factors that lead to a productive and fulfilling life. Both Rogers and Maslow believed that humans strive to develop a sense of self and are motivated to personally grow and fulfill their potential. This is in stark contrast to the psychoanalytic tradition, which focused on disorders and animal instincts. The humanistic perspective also contrasted with behaviorism in proposing that humans had the freedom to act and a rational mind to guide the process.

THE COGNITIVE REVOLUTION Whereas behaviorism dominated psychology in the United States, many European psychologists were more open to studying cognition—mental processes such as memory and perception. Starting in the late 1800s, German psychologist Hermann Ebbinghaus (1850-1909) produced reams of data on remembering and forgetting. The results of his studies produced numerous forgetting curves, graphs that show that most of what a person learns will be forgotten rapidly, but then forgetting slows to a crawl. The forgetting curve remains a staple of modern psychology, and you will read more about Ebbinghaus in Module 7.2.

Another precursor to cognitive psychology was Gestalt psychology, an approach emphasizing that psychologists need to focus on the whole of perception and experience, rather than its parts. (Gestalt is a German word that refers to the complete form of an object; see Figure 1.6.) This contrasts with the structuralist goal of breaking experience into its individual elements. For example, if Wundt were to hand you an apple, you would not think, "Round, red, has a stem..." unless he

Figure 1.6 The Whole Is Greater than the Sum of its Parts

The Gestalt psychologists emphasized humans' ability to see whole forms. For example, you probably perceive a sphere in the center of this figure, even though it does not exist on the page.

asked you to. Instead, you would likely think, "This is an apple." This simple observation led Gestalt psychologists to argue that perception and thought occur at higher, more organized levels than Wundt believed. To them, Wundt's structuralism made about as much sense as understanding water only by studying its hydrogen and oxygen atoms.

In the 1950s, the scientific study of cognition was becoming accepted practice in US psychology. The recent invention of the computer gave psychologists a useful analogy for understanding the mind (the software of the brain). Linguists argued that grammar and vocabulary were far too complex to be explained in behaviorist terms; the alternative was to propose abstract mental processes. There was a great deal of interest in memory and perception as well, but it was not until 1968 that these areas of research were given the name "cognitive psychology" by Ulrich Neisser (1928–2012). These events ushered in a new era of psychology in which studies of mental processes and experiences flourished. *Cognitive psychology* is a modern psychological perspective that focuses on processes such as memory, thinking, and language.

#### SOCIOCULTURAL PERSPECTIVES IN PSYCHOLOGY

As structuralism and functionalism were taking shape in the late 1800s and early 1900s, psychologists were starting to examine how other people influence individual behavior. A US psychologist, Norman Triplett (1861–1931), conducted one of the first formal experiments in this area, observing that cyclists ride faster in the presence of other people than when riding alone. Triplett published the first social psychology research in 1892, and a few social psychology textbooks appeared in 1908.

Despite the early interest in this field, studies of how people influence the behavior of others did not take off until the 1940s. Interest in social and cultural perspectives grew out of collaborations between sociologists (who studied populations of humans) and psychologists (who were studying individuals), in part to try to make sense of the brutality of World War II. They attempted to understand how normal

individuals could be transformed into ruthless prison camp guards, how political propaganda affected people, and how society might address issues of ethnic prejudice.

Kurt Lewin (1890–1947) is often cited as the founder of modern social psychology. Trained as a Gestalt psychologist, Lewin shifted his attention to race relations in the United States. After studying relations between individuals of different groups, he made an observation that is still well known among social psychologists: Behavior is a function of the individual and the environment, or  $B = f\{I,E\}$ . What Lewin meant was that all behaviors could be predicted and explained through understanding how an individual with a specific set of traits would respond in a context that involved a specific set of conditions. Take two individuals as an example: One tends to be quiet and engages in solitary activities such as reading, whereas the other is talkative and enjoys being where the action is. Now put them in a social situation, such as a wedding reception or a funeral. How will the two behave? Given the disparity between the individuals and between the two settings, we would suspect different behaviors would emerge.

The trends that emerged during this period laid the foundation for modern perspectives and theories in psychology. Psychology had become a clearly established discipline with established university departments, professional organizations, and academic journals. Although modern technology, such as brain scans and computing, would likely baffle psychology's founders, we believe they would find the results of modern research absolutely relevant to their own research questions. In the next module, we will explore the settings in which this broad array of psychologists are encountered and what they contribute to society.

### JOURNAL PROMPT

**The Diversity of Psychology:** Students are often surprised to learn the breadth of approaches that psychologists take to understanding behavior. Describe the most unexpected piece of information you learned about psychology in reading this module.

### Table 1.2 Areas of Specialization within Psychology

Apply your knowledge to distinguish among different specializations in psychology. You should be able to read a description of a psychologist on the left and match that individual's work to a specialization on the right.

- I am an academic psychologist who studies various methods for improving study habits. I hope to help people increase memory performance and become better students. I am a(n) \_\_\_\_\_\_.
- 2. My work focuses on how the presence of other people influences an individual's acceptance of and willingness to express various stereotypes. I am a(n) \_\_\_\_\_\_.
- 3. I have been studying how childrearing practices in Guatemala, the United States, and Cambodia all share some common elements, as well as how they differ. I am a(n) \_\_\_\_\_\_.
- 4. I am interested in behaviors that are genetically influenced to help animals adapt to their changing environments. I am a(n) \_\_\_\_\_\_.
- 5. I help individuals identify problem areas of their lives and ways to correct them, and guide them to live up to their full potential. I am a(n) \_\_\_\_\_\_.

- a. social psychologist
- b. cross-cultural psychologist
- c. cognitive psychologist
- d. humanistic psychologist
- e. evolutionary psychologist

# **Module 1.2** Summary

### 1.2a Know . . . the key terminology of psychology's history:

behaviorism clinical psychology determinism empiricism functionalism Gestalt psychology humanistic psychology materialism nature and nurture relationships psychoanalysis psychophysics structuralism zeitgeist

### 1.2b Understand ... how various philosophical ideas and scientific fields became major influences on psychology.

The philosophical schools of determinism, empiricism, and materialism provided the background for a scientific study of human behavior. The first psychologists were trained as physicists and physiologists. Fechner, for example, developed psychophysics, whereas Titchener looked for the elements of thought. Darwin's theory of natural selection influenced psychologist William James's idea of functionalism, which is the search for how behaviors may aid the survival and reproduction of the organism.

### 1.2c Apply . . . your knowledge to distinguish among the different specializations and schools of thought in psychology.

Psychology is a broad field that arose from the combination of multiple influences. These factors are reflected by the diverse interests and perspectives in modern psychology, such as cognitive and social psychology. Table 1.2 provided an opportunity to match terms to examples.

### **1.2d** Analyze ... how the philosophical ideas of empiricism and determinism are applied to human behavior.

Psychology is based on empiricism, the belief that all knowledge—including knowledge about human behavior is acquired through the senses. All sciences, including psychology, require a deterministic viewpoint. Determinism is the philosophical tenet that all events in the world, including human actions, have a physical cause. Applying determinism to human behavior has been met with resistance by many because it appears to deny a place for free will.

# Module 1.2 Quiz

#### Know . . .

- 1. In philosophical terms, a materialist is someone who believes that:
  - A. money buys happiness.
  - **B.** species evolve through natural selection.
  - C. personality can be measured by feeling for bumps on the surface of the skull.
  - **D.** everything that exists, including human beings, are composed exclusively of physical matter.

#### Understand . . .

- 2. Charles Darwin revolutionized biology by offering natural selection as an explanation for how physical characteristics of species evolved. How has his work influenced contemporary psychology?
  - A. It shows that the biological approach to studying psychology is most important.
  - B. Natural selection has encouraged people to think more scientifically in general.
  - C. Evolutionary thought shows that psychology must be limited to the study of humans.
  - **D.** Darwin applied his theory to behaviors such as emotional expressions, showing that natural selection is an important factor in understanding psychology.

- 3. A distinct feature of behaviorism is its:
  - A. search for the deeper meaning of human existence.
  - **B.** search for patterns that create a whole that is greater than its parts.
  - C. use of introspection.
  - D. exclusive emphasis on observable behavior.

### Apply . . .

- 4. Jana uses research about how we cope with stress in order to help people with psychological disorders. Jana is probably \_
  - A. an empiricist
- C. a clinical psychologist
- **B.** a supporter of eugenics
- D. a phrenologist

### Analyze . . .

- 5. The field of psychoanalysis arose from speculation that biological forces, rather than rational thinking, controlled behavior. This is in stark contrast to the humanistic psychologists who emphasized each individual's ability to control his or her life. On which philosophical element of psychology do these two schools of thought disagree?
  - A. determinism
- C. nature or nurture
- **B.** structuralism
- D. functionalism

# Module 1.3 Putting Psychology to Work: Careers in Psychology and Related Fields

# Learning Objectives

- **1.3a** Know . . . the key terminology of psychological professions.
- **1.3b** Understand . . . the various professional settings occupied by psychologists.
- **1.3c** Understand . . . the distinctions among mental health professions in their approaches and educational requirements.

When you picture a psychologist at work, do you imagine one operating a huge chainsaw and cutting a hole through three feet of ground-level ice? What if the psychologist happened to be in Antarctica studying the behavior of seals and was creating the hole so that he could capture a glimpse of what these animals were doing beneath the ice? This would describe at least part of the career of Jesse Purdy, a psychology professor who spent many months in Antarctica recording the social behavior of Weddell

- **1.3d** Apply . . . your knowledge to identify the job title of a psychologist based on their
- **1.3e** Analyze . . . the claim that psychologists could contribute to virtually any field of work.

seals. When not cutting holes through ice and observing seals, Purdy teaches psychology courses to undergraduate students and conducts research on a quirky animal called the cuttlefish, a close relative of the octopus. This probably sounds like a far cry from what the stereotypes of psychologists suggest Purdy is supposed to do. Granted, this example is not exactly mainstream, but it does attest to the wide range of topics and settings where you will find psychologists at work.

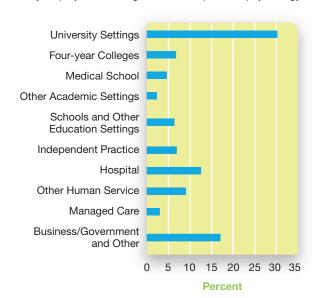

### Professions in Psychology

Psychology is a broad discipline with many applications in the workplace. You will see a wide variety of job titles and descriptions in this module, including some jobs that are not labeled as psychology but are closely aligned to it. Despite the diverse roles described here, remember that these are applications of psychology, which means they involve a scientific approach to behavior and thought. Those who earn a doctoral degree in psychology work in a variety of settings, with the most common being in mental health settings, or engaged in research and teaching at colleges and universities (Figure 1.7).

**RESEARCH AND TEACHING** Research psychologists typically work at universities, in corporations, in the military, and in governmental agencies (such as the National Institutes of Health and Mental Health). Many psychologists working in these different settings focus on applying basic principles of psychology to real-world settings. **Applied psychology** uses psychological knowledge to address problems and issues across various settings and professions, including law, education, clinical psychology, and business organization and management. Some applied psychologists do both basic and applied work; it really depends on where a psychologist is employed.

Your psychology instructor is employed (at least part of the time) in academic psychology. Academic psychologists work at colleges and universities, and most combine teaching with conducting research, although some do only one or the other. Psychologists working in academics are not likely to refer to themselves as academic psychologists, however. For example, most instructors of psychology

Figure 1.7 Where Professional Psychologists Work Primary employment settings for PhD recipients in psychology.

courses would describe themselves by their specialization, as in "I am a social psychologist" or "I am a developmental psychologist."

#### **PSYCHOLOGICAL HEALTH AND WELL-BEING**

Generally when most people hear the word psychology, they think first of mental health. In fact, the depiction of a psychologist with notepad in hand listening attentively to a client has become an all-too-common caricature, reinforcing the belief that psychologists are in the business of analyzing people. Clearly, the mental health field is the largest sector of employment for individuals with advanced degrees in psychology. However, helping professions are not limited to individuals with psychology degrees, as shown in Table 1.3. In fact, we call mental health jobs the helping professions because helping is what they all have in common, not the specific educational criteria, degrees, or occupational roles.

Multiple job descriptions are necessary for differentiating the distinct treatments considered the most effective for each individual helping profession. For example, **psychiatry** is a branch of medicine concerned with the treatment of mental and behavioral disorders. As physicians, psychiatrists can and are likely to prescribe drugs such as antidepressants. Clinical and counseling psychologists, however, treat mental health concerns and disorders with psychological approaches. Social workers are likely to emphasize the social context of the individuals in treatment, such as the family's dynamics, socioeconomic status, and community.

The educational levels required of each helping profession vary depending on the role. Psychologists may work with a master's degree in most states, but many go on to pursue doctorates, which provide greater career opportunities. This might include the typical graduate degree for a scientific discipline, the Doctor of Philosophy (Ph.D.), which combines training in scientific research and practice. However, there is also a specialized Doctor of Psychology (Psy.D.) degree that focuses almost exclusively on the practice of psychology.

As you can see, mental health providers can be found in many settings and provide numerous services to people in need. The caricature of a psychologist as an analyst breaks down even more when we expand our discussion of what psychologists do.

Psychologists can specialize to practice in specific contexts. Forensic psychology encompasses work in the criminal justice system, including interactions with the legal system and its professionals. The field is often glorified in movies and TV as criminal profiling and investigation, but it is actually a practical profession involving little of what is portrayed in these shows. The relatively few criminal profilers work with the FBI and larger law enforcement agencies to develop a set of characteristics that are statistically

Table 1.3 Employment in Psychology

Common occupations in the area of mental health, their educational requirements, and the basic roles for each position.

Job Title	Education	Role
Clinical psychologist or Counseling psychologist	Ph.D. or Psy.D.	Diagnosis and treatment of psychological disorders
Neuropsychologist	Ph.D. or Psy.D.	Diagnosis and evaluation of individuals with neurological damage
School psychologist	Ed.D., Ph.D., or master's	Diagnosing behavioral problems and learning disabilities; working in schools to develop personalized programs to help students
Community psychologist	Ph.D. or Psy.D.	Providing basic mental health services to the community with a focus on education and prevention
Licensed Mental Health Counselor	Master's in Psychology or Marriage & Family Therapy	Providing individual and group counseling for individuals and families experiencing mental health problems
Licensed clinical social worker	Master's in social work (MSW)	Counseling individuals and families experiencing mental health and social problems; engaging in community organizations and providing social services
Forensic psychologist	Ph.D. or Psy.D.	Psychology related to judiciary or criminal issues, such as evaluating an individual's competency to stand trial
Psychiatrist	Medical doctor, M.D.	Diagnosis and treatment of psychological disorders with an emphasis on a medical perspective
Psychiatric nurse	Nursing degree, RN	Working as part of a comprehensive treatment team to manage medical and behavioral treatments on a regular basis
Behavioral health technician; case manager	Bachelor's degree	Assisting with treatment on either an inpatient or outpatient basis, respectively

related to a criminal's methods. You would more likely see forensic psychologists working in prisons, training and evaluating police officers, or assisting with jury selections and evaluating whether defendants are able to stand trial.

School psychology involves working with students who have special needs, such as those with emotional, social, or academic problems. Practitioners might address ways to change troubling or disruptive behavior, or a cognitive disability that interferes with learning, such as dyslexia. School psychologists may spend a lot of time observing a child's behavior or administering special psychological tests to identify learning disabilities. These professionals rarely work alone; instead, they are more often part of students' educational teams, which include their parents, teachers, and counselors.

Most of the helping professions we have described have two things in common: (1) graduate degrees (more school after college!) and (2) licensure or certification as approved by individual states. More school and licensing tests may or may not sound appealing; certainly many individuals prefer to start their careers immediately after college rather than going for another degree. With a bachelor's degree, individuals can work in treatment settings on a more basic level. For example, case managers make regular contact with individuals to ensure they are complying with treatment (e.g., taking medication as prescribed) and make sure their clients are in touch with public and private services that may help them. Behavioral health technicians have similar tasks, except they are for the short term (usually less than 30 days) and on an inpatient basis.

HEALTH AND MEDICAL PROFESSIONS In addition to providing for mental health, an increasing number of psychologists are focusing on physiological health in the field known as health psychology (or behavioral medicine), the study of how individual, biological, and environmental factors affect physical health. Health psychologists identify the behaviors and personality traits that put people at risk and that, when combined with an unfortunate genetic heritage or infection, lead to disease. For example, overeating, poor food choices, and a sedentary lifestyle have been linked to diabetes and a variety of cardiovascular ailments. Psychological traits such as pessimism and hopelessness are correlated with impaired immune functioning and lower recovery rates from major surgeries, diseases, or accidents. Working long hours at a high-stakes job while sacrificing rich and meaningful relationships can affect one's health as well. Thus, psychologists who work in the health fields might be seen as the behavioral counterparts to practitioners of traditional medicine. Whereas physicians treat the physiological aspects of a disease, psychologists help to change the related behaviors. Health psychology is the focus of Chapter 16.

**PSYCHOLOGY IN THE CORPORATE WORLD** One of the fastest-growing fields within psychology is **industrial and organizational (I/O) psychology**, which is a branch of applied psychology in which psychologists work for businesses and other organizations to improve employee productivity and the organizational structure of the company or business.

I/O psychologists may develop tests to hire workers who have the best chance at succeeding, they may assist work teams to improve communication and responsibility, and they may help organizations with the management of change. This approach to psychology is covered in depth in Chapter 17.

Closely related to I/O psychology is human factors psychology, which is the study of how people interact with tools, physical spaces, or products. This is the high-tech branch of applied psychology; a great deal of human factors work applies principles of sensation and perception to complex work environments such as aircraft cockpits or laparoscopic surgical devices. Human factors psychologists may study human-computer interaction to develop user-friendly software and other products. Similarly those who practice environmental psychology study factors that improve working and living conditions, but they do so by establishing how the environment affects individuals or groups. Results from this type of research may be used in the design of working and living spaces to foster communication, to reduce distractions, and to prevent or reduce strain, stress, and fatigue.

Many undergraduates who major in psychology go on to marketing and advertising. (In Module 1.2, we mentioned that psychologist Watson made a successful career for himself in advertising.) What does marketing have to do with psychology? A great deal, it turns out. Marketing involves a lot of research on what consumers prefer, what buyers expect, and what makes shoppers choose one product over another. Marketing professionals conduct surveys and experiments on preferences, such as the taste tests we see reported on television commercials.

### JOURNAL PROMPT

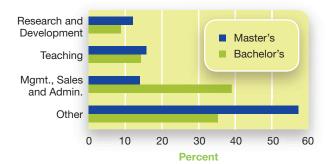

**Specializations in Psychology:** If you were to enter the field of psychology, which area of specialization described in this module would you most likely choose? Why?

#### I'M NOT PLANNING ON A CAREER IN PSYCHOLOGY...

Not wanting to become a psychologist is fine, too; the world needs many types of professionals. Based on recent trends, only a small percentage of this year's nearly 100,000 bachelor-level psychology graduates will go on to work in psychological fields—far more (approximately 40%) will go on to work in business settings (Magaletta et al., 2010). But students who major or minor in psychology will be able to apply what they have learned in many different types of work. Because of psychology's emphasis on research methods, psychology majors turn out to be excellent problem solvers and critical thinkers. Also, psychology majors learn many principles of human behavior, ranging from individual cognition to group dynamics. These skills are needed for marketers, managers, and teachers (see Figure 1.8). So an understanding of behavior works to your advantage regardless of which career you eventually choose.

Even if this is the only course you take in psychology, we hope you enjoy it. We also hope that you come to understand more than just a few principles about human behavior. We anticipate that you will become more aware of the evidence people use when they make claims about behavior. Remember, as members of a capitalist society, our warning is *caveat emptor*—"Buyer, beware!"

**Figure 1.8** Work Settings for People Earning Master's and Bachelor's Degrees in Psychology

### Table 1.4 Matching Psychologist Titles and Roles

Identify the appropriate job title for each psychologist in the table. For every job description on the left, there is one correct title on the right.

- 1. I am employed at a state penitentiary and work closely with parole officers to make sure parolees have a psychological treatment plan to address substance abuse, anger management, impulsiveness, and other problems. I am a(n)
- 2. I conduct research for the military to ensure that computer systems in aircraft are as user friendly as possible. I am a(n) \_\_\_\_\_.
- 3. I went to medical school and then began working at a hospital, where I treat severe psychological disorders with medications and some psychotherapy. I am a(n) \_\_\_\_\_\_.
- 4. I am an independent consultant, and I try to help businesses identify and hire the best possible executives. I am a(n) \_\_\_\_\_\_.
- 5. Although I did not go to medical school, I have been working with heart surgery patients to help them adjust to life after surgery. This involves psychotherapy to deal with emotions and stress, as well as helping the patients adopt healthier behaviors. I am a(n) \_\_\_\_\_\_.

- a. health psychologist
- b. psychiatrist
- c. forensic psychologist
- d. human factors psychologist
- e. I/O psychologist
